TECHNICAL NOTE 3476

CALCULATED SPANWISE LIFT DISTRIBUTIONS AND
AERODYNAMIC INFLUENCE COEFFICIENTS FOR
SWEPT WINGS IN SUBSONIC FLOW

By Franklin W. Diederich and Martin Zlotnick

SUMMARY

Spanwise lift distributions have been calculated for 61 swept wings with various aspect ratios and taper ratios and with a variety of angle-of-attack or twist distributions, including flap and aileron deflections, by means of the Weissinger method with eight control points on the semi-span. Also calculated for these plan forms were aerodynamic influence coefficients which pertain to a certain definite set of stations along the span. The information presented herein can thus be used both in the analysis of untwisted wings or wings with known twist distributions and in aeroelastic calculations involving initially unknown twist distributions.

This paper supplements and is intended to be used in conjunction with NACA TN 3014, where the same type of information, calculated in the same way, is presented for 19 unswept wings.

INTRODUCTION

In the design of an airplane, a knowledge of the spanwise lift distribution on the wing is important in predicting structural loads and stability characteristics. For high-speed airplanes having flexible wings, the calculation of the spanwise lift distribution is an aeroelastic rather than a purely aerodynamic problem. In aeroelastic calculations, means are required for calculating the spanwise lift distribution expressed in terms of angle-of-attack (or twist) distributions which are initially unknown. Aerodynamic influence functions and coefficients are the most convenient means of accomplishing this purpose.

Several methods for calculating such aerodynamic influence functions and coefficients at arbitrary spanwise stations are developed and discussed in detail in reference 1. These methods employ either aerodynamic influence coefficients for prescribed spanwise stations or lift distributions for various prescribed continuous and discontinuous angle-of-attack conditions. For subsonic flow the required numerical values of

these quantities are presented in reference 1 for 19 unswept wings having various aspect ratios and taper ratios. The calculations were made on the Bell Telephone Laboratories X-66744 relay computer at the Langley Laboratory. A convenient matrix formulation of the Weissinger L-method, with eight control points on the semispan was used.

In the present paper, numerical results corresponding to those given in reference 1 are presented for 61 swept wings in subsonic flow. The calculations of the present paper have been made in the same manner as those of reference 1 and may be used in the same way. For instance, the methods described in the body and the appendixes of reference 1 for calculating aerodynamic influence functions and influence coefficients at arbitrary spanwise stations can be used in conjunction with the information presented herein because they apply to any sweep angle. The present paper may, therefore, be considered a supplement to reference 1, and in order to facilitate its joint use with reference 1 the calculated information is presented herein in the same way as in reference 1.

SYMBOLS

A	aspect ratio
b	wing span
b_{ail}	aileron span
b_f	flap span
C_{BM}	root bending-moment coefficient for unit angle of attack, $\frac{4 \times \text{Bending moment}}{qSb}$
C_{D_i}	induced-drag coefficient at a unit angle of attack
C_L	lift coefficient at a unit angle of attack
$C_{L_{1/2}}$	lift coefficient for one semispan of antisymmetrically loaded wing at a unit tip angle of attack, $\frac{L_{1/2}}{\frac{q}{2} \frac{S}{2}}$
C_{L_a}	lift-curve slope per radian for additional-type loading

c_l rolling-moment coefficient

$$c_{ld} = -c_{lp}$$

c_{lp} coefficient of damping in roll

c wing chord

c^* dimensionless chord, $\frac{c}{b/2}$

\bar{c} average chord, S/b

c_l section lift coefficient

$L_{1/2}$ lift on one semispan

M free-stream Mach number

q dynamic pressure

S wing area

V free-stream speed

y lateral ordinate

y^* dimensionless lateral ordinate, $\frac{y}{b/2}$

\bar{y} lateral ordinate of center of pressure of one semispan

α angle of attack, radians

Γ vortex strength

Γ^* dimensionless vortex strength or loading coefficient,

$$\frac{4\Gamma}{bV} = c^* c_l$$

Λ angle of sweepback at the quarter-chord line, deg

λ taper ratio, c_t/c_r

PRESENTATION OF RESULTS

Spanwise Lift Distributions

Geometric characteristics of the 61 plan forms treated in this paper are given in table I. These plan forms, together with the 19 plan forms considered in reference 1, are also shown in figure 1. Lift distributions due to the following continuous symmetric and antisymmetric angle-of-attack distributions have been calculated for each of the 61 plan forms.

Symmetric angle-of-attack distributions:

Constant	$(\alpha = 1)$
Linear	$(\alpha = y^*)$
Quadratic	$(\alpha = y^{*2})$
Cubic	$(\alpha = y^{*3})$
Straight-line	$(\alpha = \frac{c_t}{c} y^*)$

Antisymmetric angle-of-attack distributions:

Linear	$(\alpha = y^*)$
Quadratic	$(\alpha = y^{*2} \text{ for } y^* \geq 0; \alpha = -y^{*2} \text{ for } y^* \leq 0)$
Cubic	$(\alpha = y^{*3})$
Quartic	$(\alpha = y^{*4} \text{ for } y^* \geq 0; \alpha = -y^{*4} \text{ for } y^* \leq 0)$
Quintic	$(\alpha = y^{*5})$

The straight-line angle-of-attack condition was included to represent actual structural twists where the surface of the wing is generated by straight lines so that the product $c^*\alpha$, the deflection of the leading edge, varies linearly with y^* ; that is

$$c^*\alpha = c_t^*y^*\alpha_t$$

or, for unit twist at the tip,

$$\alpha = \frac{c_t^*}{c^*} |y^*|$$

For untapered wings, the straight-line lift distribution is the same as the linear lift distribution, and for wings of zero taper ratio, it is undefined.

Lift distributions for flap-type and aileron-type angle-of-attack distributions are also presented. A correction has been made for the discontinuity in angle of attack by the method of appendix B of reference 1; this correction insures that the accuracy of the lift distributions for the discontinuous angle-of-attack conditions is of the same order as that for the continuous angle-of-attack conditions. The values of b_f/b and b_{ail}/b (ratios of the flap span to the total span and the aileron span to the total span, respectively) for which the lift distributions have been calculated are 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, and 1.0. As is usual, the flaps have been taken to be inboard and the ailerons outboard. The lift distribution for any flap or aileron configuration may be obtained, however, by linear superposition; thus, the lift distribution for an outboard flap extending, for example, from $y^* = 0.5$ to $y^* = 1.0$ can be obtained by subtracting the lift distribution for the inboard flap ($b_f/b = 0.5$) from the additional lift distribution ($b_f/b = 1.0$). A similar procedure can be used for inboard ailerons.

The lift distributions for the 61 plan forms considered are presented in figures 2 to 62. Table I serves as a table of contents for this group of figures. Parts (a) and (b) of each figure contain the lift distribution due to symmetric and antisymmetric continuous angle-of-attack distributions, respectively, for a given plan form, and parts (c) and (d) contain the lift distribution due to flaps and ailerons respectively, for the same plan form.

Aerodynamic Parameters

The aerodynamic parameters $C_{L\alpha}$, C_{EM} , \bar{y}^* , C_{D_i} , C_{l_d} , and $C_{L1/2}$, calculated by the method of appendix A of reference 1, are presented in table II for the plan forms considered herein. The values of C_L and C_{EM} for a unit effective flap deflection, calculated in the same manner, are presented in table III, and the values of $C_{L1/2}$ and C_l for a unit effective aileron deflection are presented in table IV.

These lift and moment coefficients pertain directly to full-chord flaps and ailerons set at an angle of attack (measured in the streamwise direction) of 1 radian. For partial-chord flaps and ailerons deflected by an angle of δ radians about their hinge lines, these coefficients must be multiplied by the quantity $\alpha_\delta \cos \Lambda_h$, where α_δ is defined in terms of section properties as

$$\alpha_\delta = \frac{\frac{\partial c_l}{\partial \delta}}{\frac{\partial c_l}{\partial \alpha}}$$

and Λ_h is the angle of sweepback of the hinge line.

Aerodynamic Influence Coefficients

for Stipulated Stations

Aerodynamic influence coefficients for symmetric and antisymmetric lift distributions were obtained by the method of appendix A of reference 1 and are presented as the matrices $[Q_s]$ and $[Q_a]$ in tables V(a) and V(b), respectively. Each influence-coefficient matrix in the table applies to a given plan form. These influence-coefficient matrices can be used to calculate the spanwise lift distribution for any continuous angle-of-attack condition from the following matrix expressions:

For the symmetric distributions,

$$\left\{ \Gamma_s^* \right\} = C_{L\alpha} [Q_s] \left\{ \alpha_s \right\}$$

For the antisymmetric distributions,

$$\left\{ \Gamma_{a}^{*} \right\} = C_{l_d} \left[Q_a \right] \left\{ \alpha_a \right\}$$

In these expressions α is the angle of attack at stations $y^* = 0.9808, 0.9239, 0.8315, 0.7071, 0.5556, 0.3827, 0.1951$, and 0, and Γ^* is the desired lift at those stations. In this paper the convention is that the angle of attack for the station nearest the wing tip ($y^* = 0.9808$) is the first element of the angle-of-attack matrix $\{\alpha\}$ and the lift at the same station is the first element of the lift distribution matrix $\{\Gamma^*\}$. The matrices $[Q_s]$ and $[Q_a]$ of table V are arranged accordingly.

If aerodynamic influence coefficients or aerodynamic influence functions are required for arbitrary stations, they may be calculated from the numerical data presented herein by the methods developed in reference 1.

DISCUSSION

The limitations of the Weissinger method have been discussed in reference 1 and elsewhere. To the extent that they apply to the results presented herein, they are summarized in the following paragraphs.

The results obtained by the Weissinger method apply only to angles of attack which are relatively small, because the method presupposes potential flow and at higher angles of attack the boundary-layer effects tend to become significant. In the case of swept wings these effects may be different from the effects on unswept wings, inasmuch as on swept wings a distinct leading-edge vortex may be formed at even moderate angles of attack. The effect of this vortex on the flow field is amenable to analytical treatment by potential-flow theory, but such an analysis is beyond the scope of this paper.

Basically, the Weissinger method applies to incompressible flow. However, by means of the three-dimensional Prandtl-Glauert rule it can be extended to compressible subsonic flow. This rule states that the pressure distribution, the lift, the rolling moment, and similar quantities for a wing with aspect ratio A , taper ratio λ , and angle of sweepback Λ flying at a subsonic Mach number M are equal to $1/\sqrt{1 - M^2}$ times the

corresponding quantities for a wing with an aspect ratio $A\sqrt{1 - M^2}$,

taper ratio λ , and angle of sweepback $\tan^{-1}\left(\frac{\tan \Lambda}{\sqrt{1 - M^2}}\right)$ flying in an

incompressible medium at the same angle of attack. At Mach numbers approaching 1 the linearizations implied by this rule tend to lose validity; however, the results of linear theory (such as the Weissinger method in conjunction with the Prandtl-Glauert rule) are more nearly valid at very high subsonic Mach numbers for wings with high angles of sweepback and low aspect ratios than for unswept wings with moderate or high aspect ratios.

Inasmuch as the side of the fuselage tends to act as a reflection plate, a sweptback or a sweptforward wing with a large fuselage is equivalent, to a certain extent, to an M or a W wing, respectively. However, calculations of the lift distributions on M wings have indicated that the effects of the spanwise discontinuities in the local angle of sweepback are largely localized, so that the effects of nacelles and fuselage on the lift distribution at low angles of attack are not likely to be much larger for swept than for unswept wings.

The Weissinger method furnishes no information concerning the local chordwise centers of pressure. Some of the available theoretical information concerning this subject is summarized in reference 2 for sweptback as well as for unswept wings.

The Weissinger idea of concentrating the lift on the quarter-chord line and satisfying the boundary condition at the three-quarter-chord line, as well as the integral equation which constitutes the mathematical expression of this idea, is valid for the purpose of calculating lift distributions on all the plan forms considered herein and in reference 1. However, the numerical method used by Weissinger and also used herein and in reference 1 for solving this equation has the shortcoming that, unless many points are considered along the span, numerical difficulties arise at the root of swept wings of high aspect ratio and on all wings with zero taper ratio. Near the root, the difficulty stems from the fact that in the numerical treatment no points are considered between the root proper and a point at 20 percent of the semispan if eight points are used along the semispan (or 40 percent if four points are used). However, for a swept wing the kernel of the Weissinger equation, that is, the $F(y, \eta)$ function of reference 1, varies rapidly near the root and, consequently, so does the lift distribution within a distance of about one-half root chord from the root. This rapid variation cannot be taken into account properly in the case of wings of moderate and high aspect ratios, for which one-half root chord amounts to only a small fraction of the semispan. Similarly, at the tip of a wing with zero taper ratio

the lift distribution goes to zero with finite slope, whereas in the numerical treatment of the Weissinger equation the assumption is implied that it goes to zero with infinite slope.

These difficulties result in incorrect values of the lift distribution not only near the root or tip, but sometimes over most of the span. Calculations by means of more accurate methods and comparison with experimental results have indicated that for highly swept wings of large aspect ratio or wings with zero taper ratio, calculations with four points on the semispan may lead to unreliable results. Consequently, eight points were used in the calculations described herein. Even so, the lift distributions are likely to be less reliable for these wings than for others, at least in the regions near the root or the tip, as the case may be.

The manner in which results of the type presented here can be used to calculate lift distributions for known and initially unknown angle-of-attack or twist distributions has been discussed extensively in reference 1; in particular, the relative merits of the various methods of obtaining aerodynamic influence functions and coefficients from such results are discussed therein at some length. The discussion is equally pertinent to the present paper and, therefore, will not be repeated here.

CONCLUDING REMARKS

For a variety of angle-of-attack conditions (including flap and aileron deflections), spanwise lift distributions and aerodynamic influence coefficients pertaining to a certain definite set of stations along the span have been calculated by means of the Weissinger method with eight control points on the semispan for 61 swept wings with various taper ratios and aspect ratios and the results are presented herein.

This information supplements that presented previously for 19 unswept wings in NACA TN 3014. It can be used in the analysis of untwisted swept wings or swept wings with known twist as well as in aeroelastic calculations involving initially unknown twist distributions.

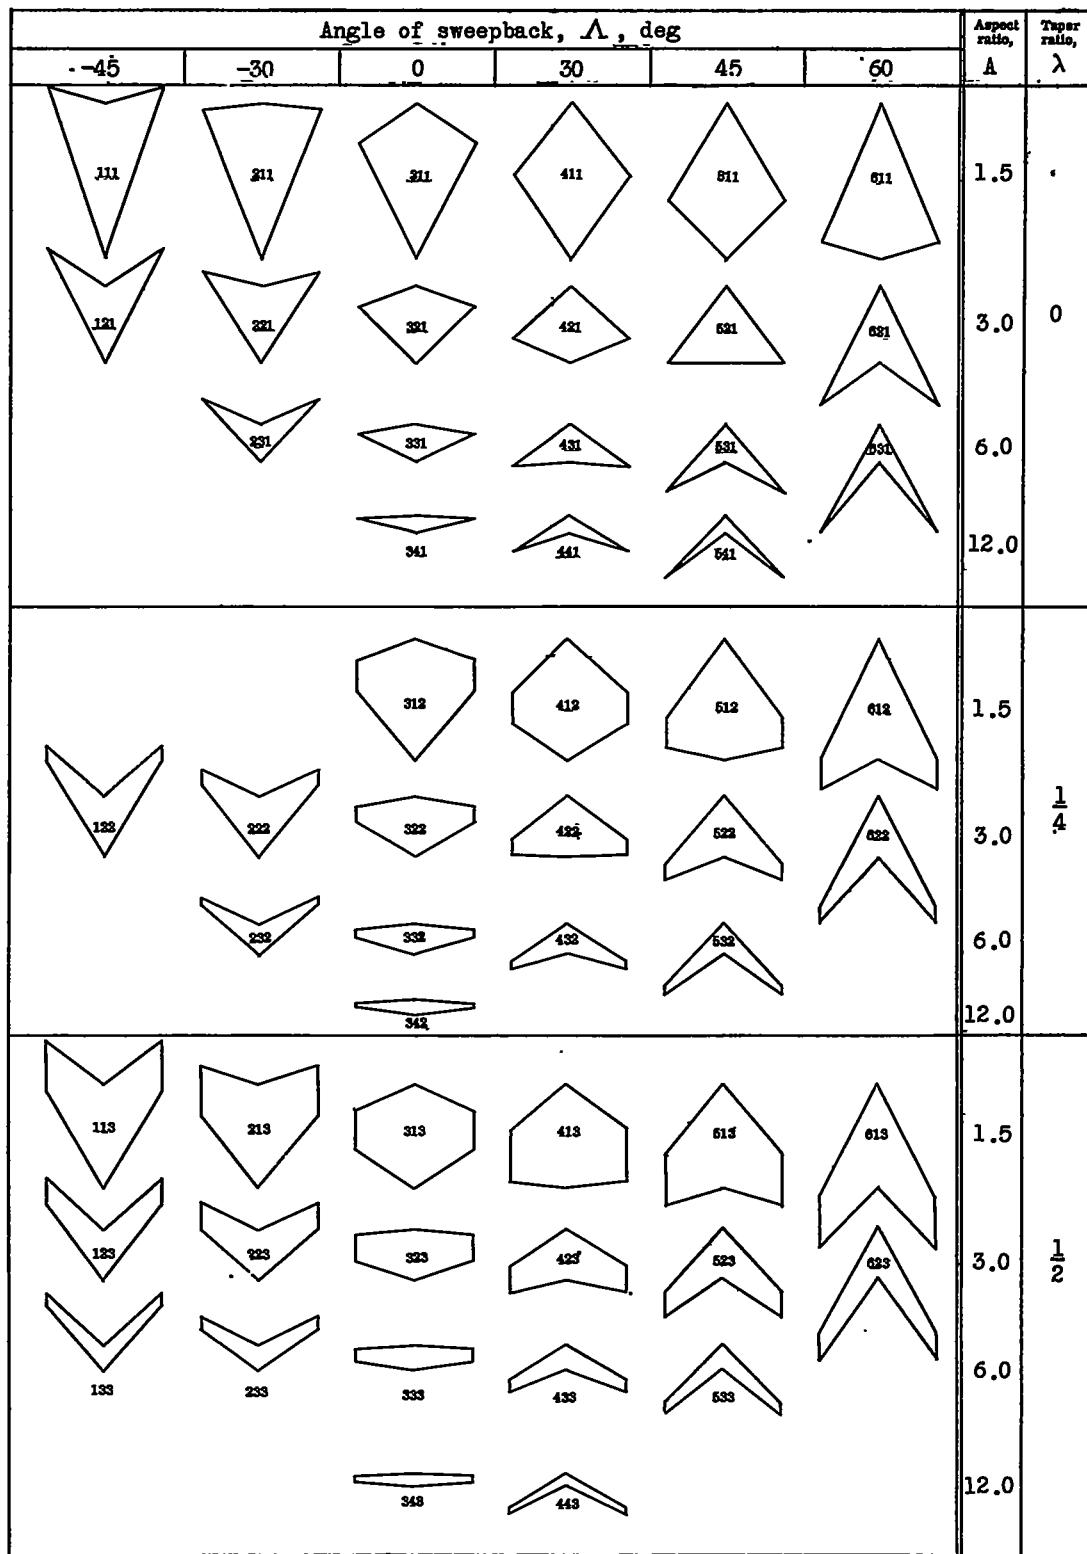

Figure 1.- Plan forms for which spanwise lift distributions are calculated.

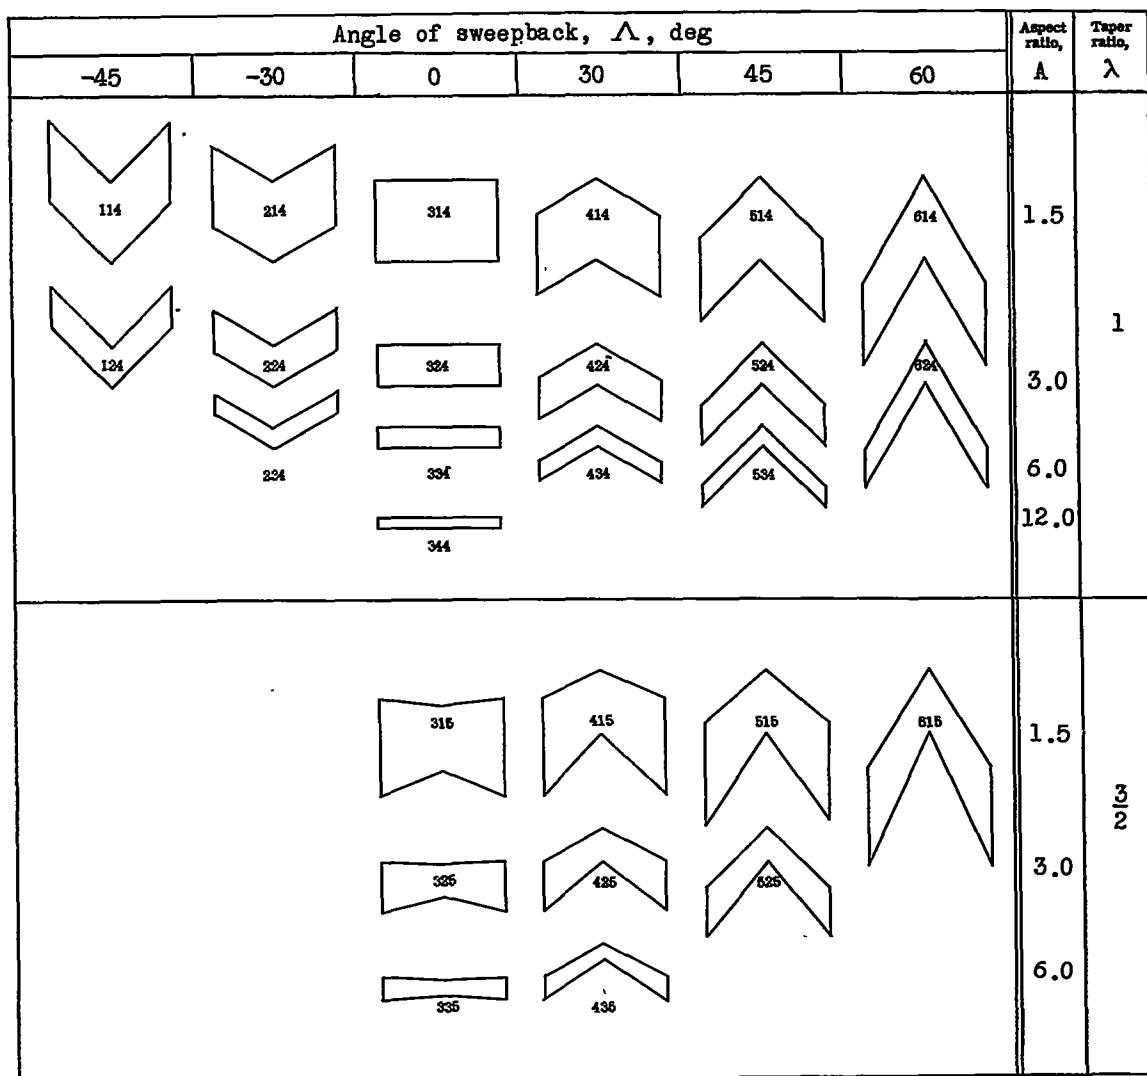

Figure 1.- Concluded.

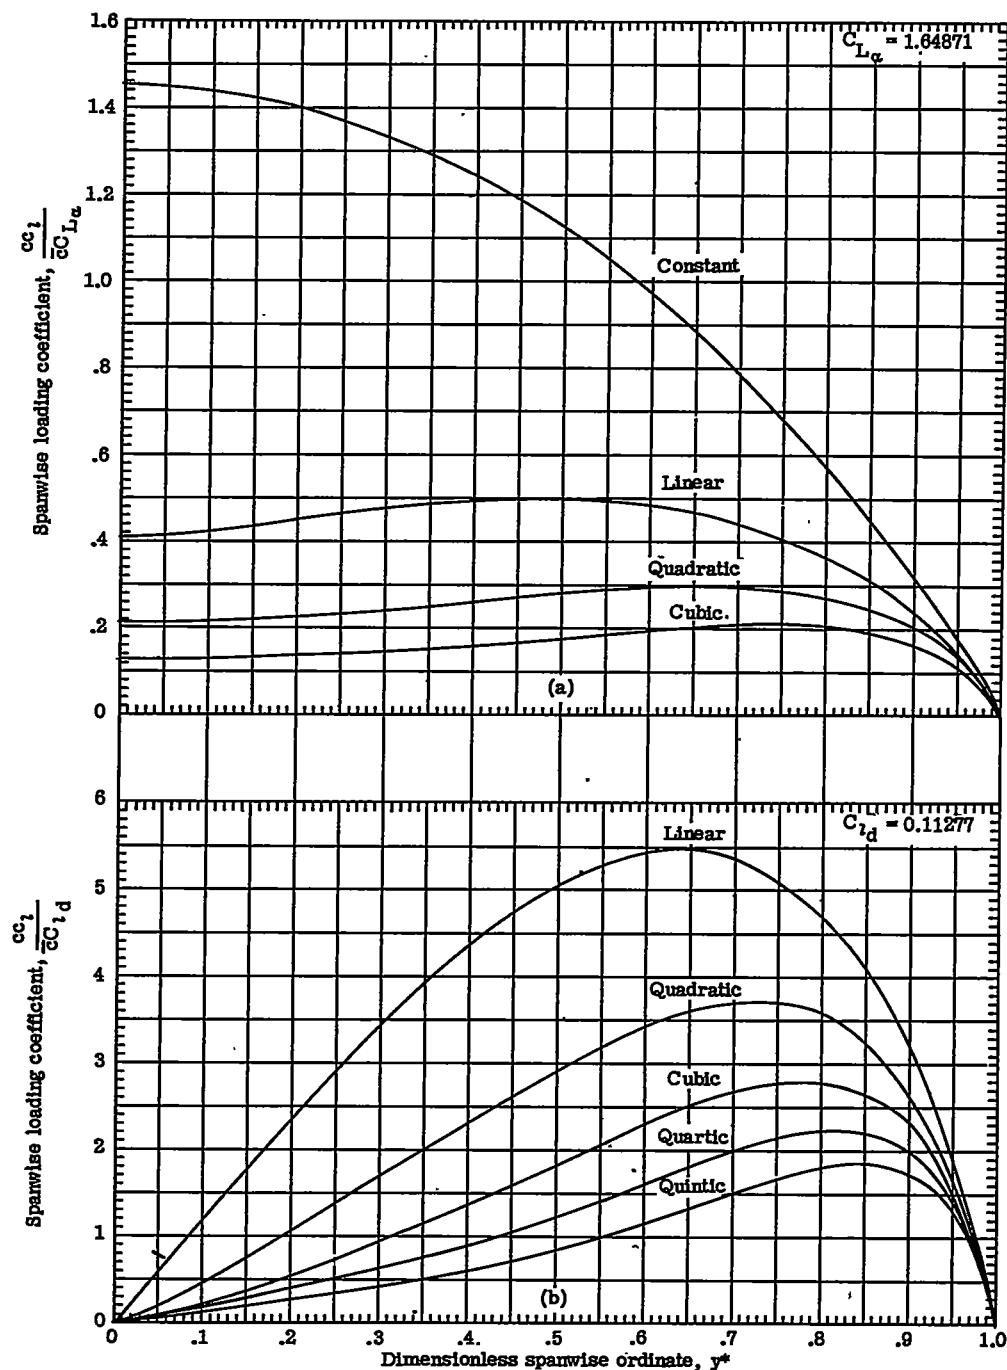

Figure 2.- Spanwise lift distributions for plan form 111 ($A = 1.5$; $\lambda = 0$; $\Delta = -45^\circ$).

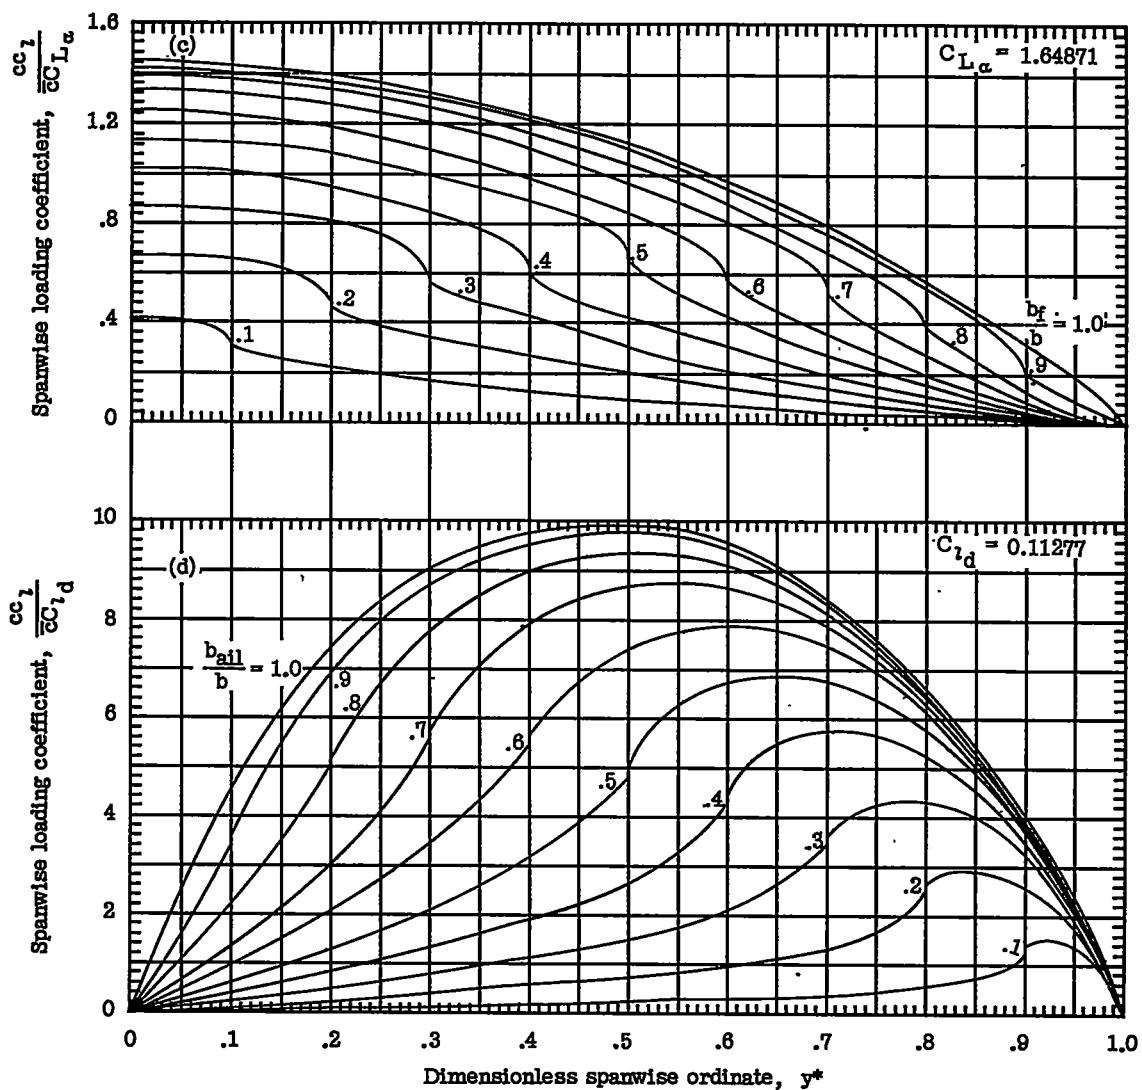

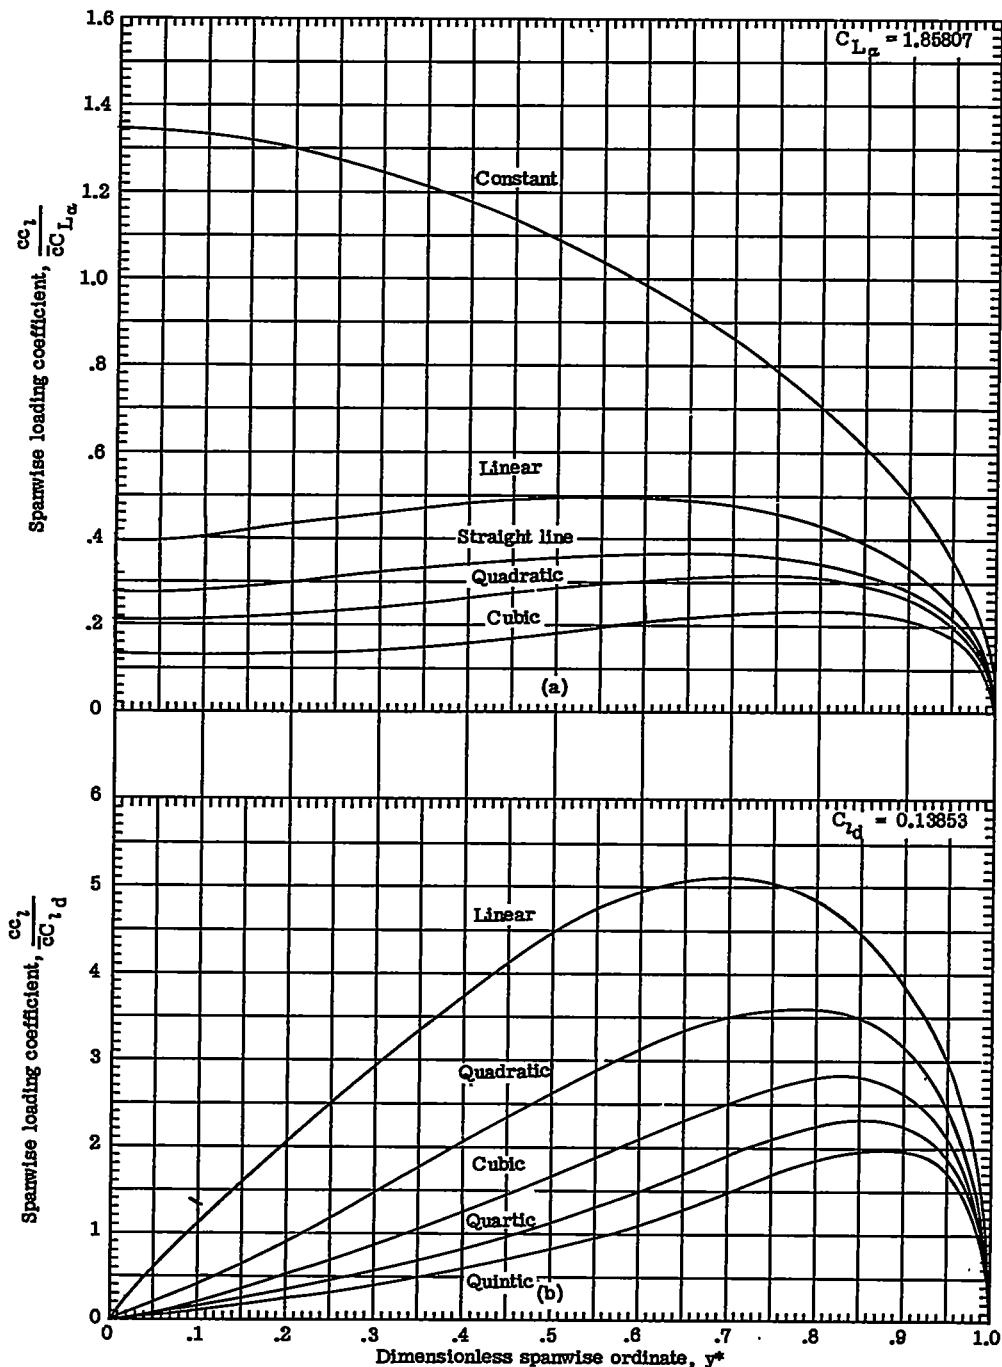

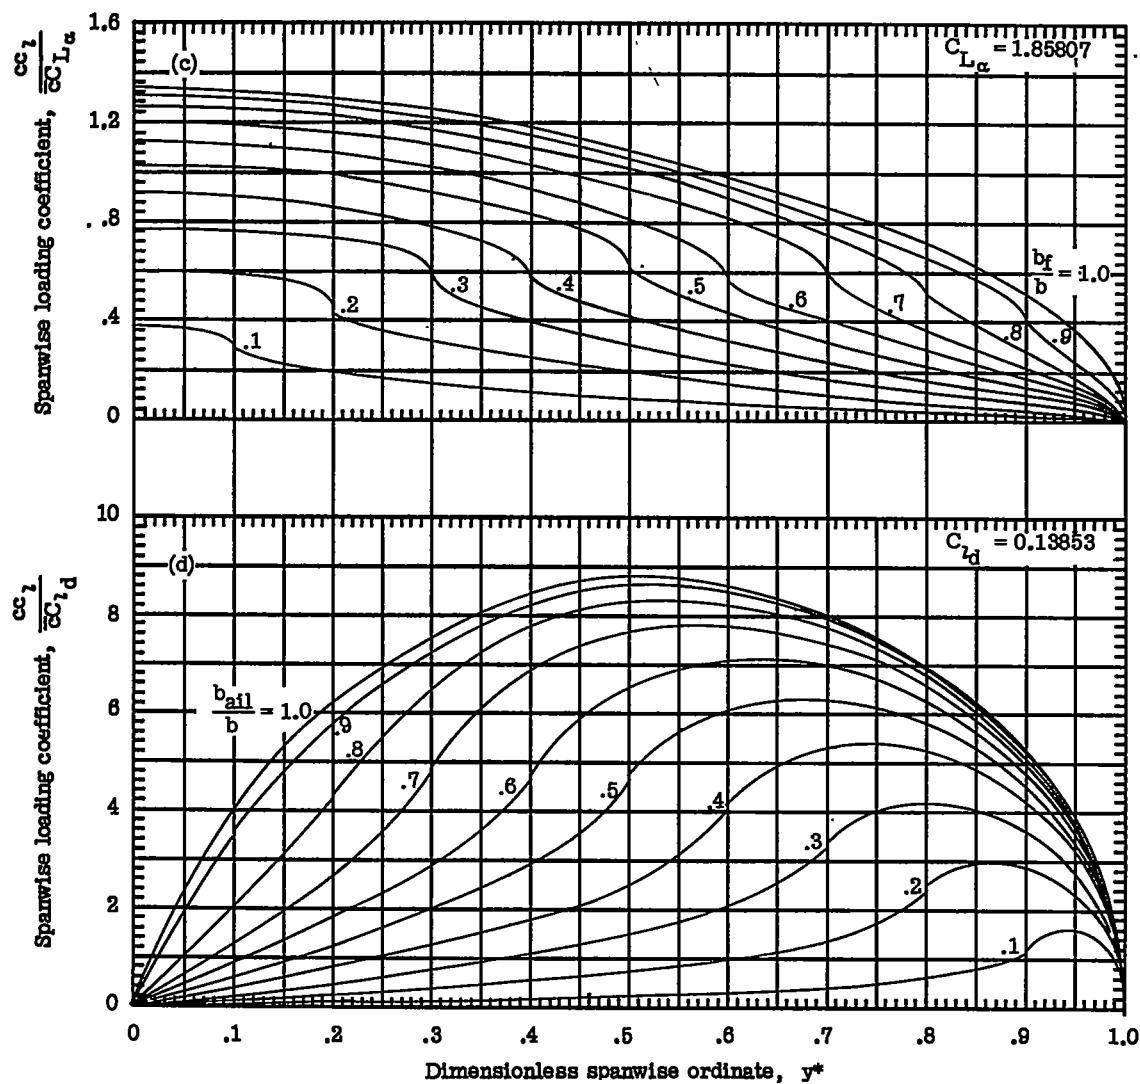

Figure 2.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

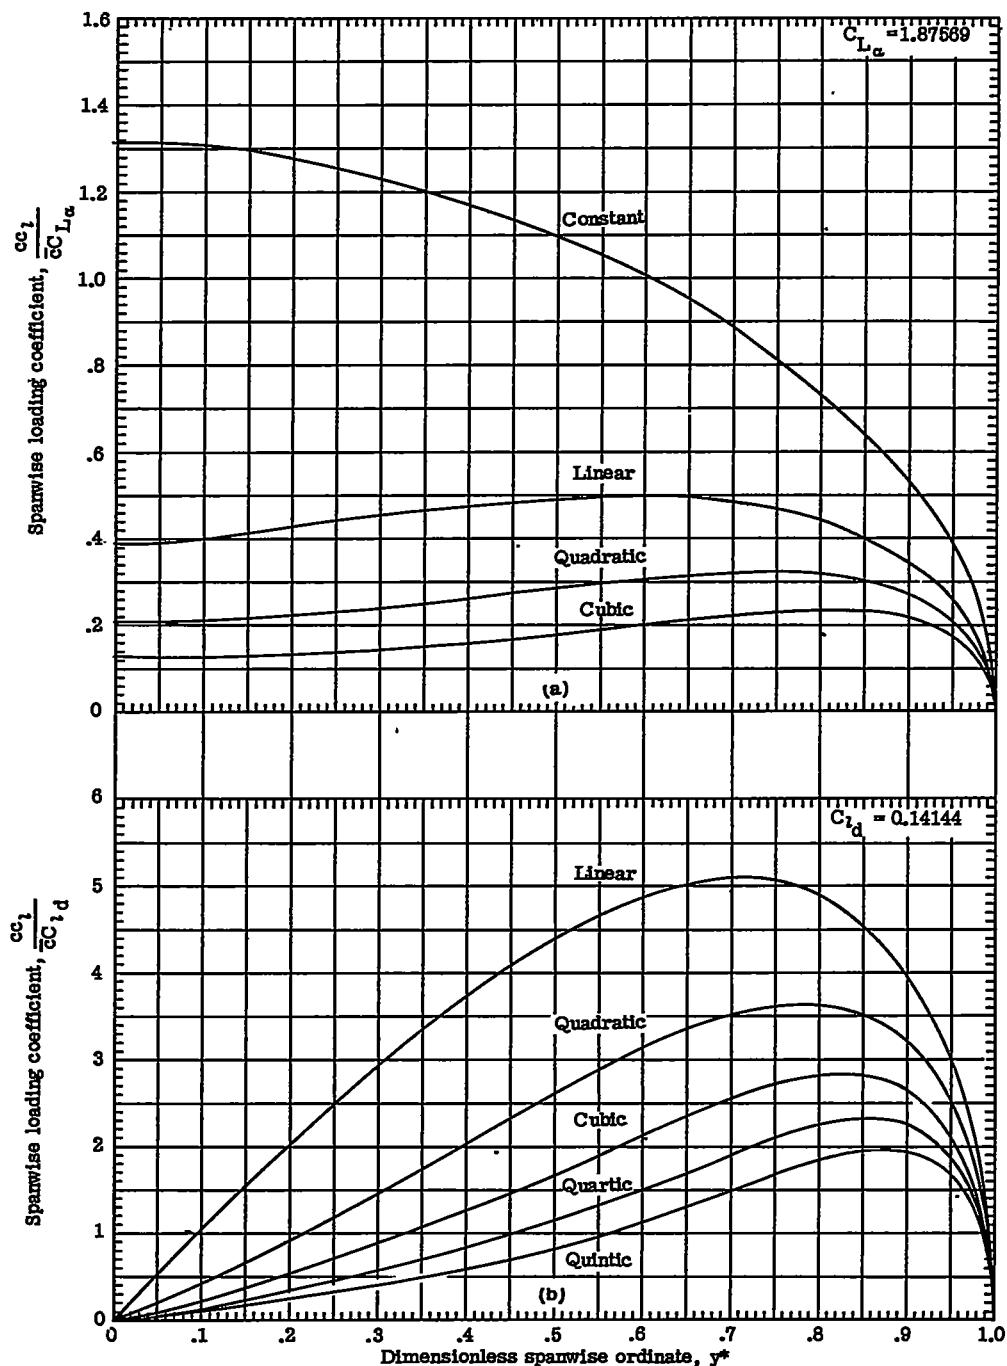

Figure 3.- Spanwise lift distributions for plan form 113 ($A = 1.5$; $\lambda = 0.50$; $\Lambda = -45^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 3.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 4.- Spanwise lift distributions for plan form 114 ($A = 1.5$; $\lambda = 1.00$; $\Lambda = -45^\circ$).

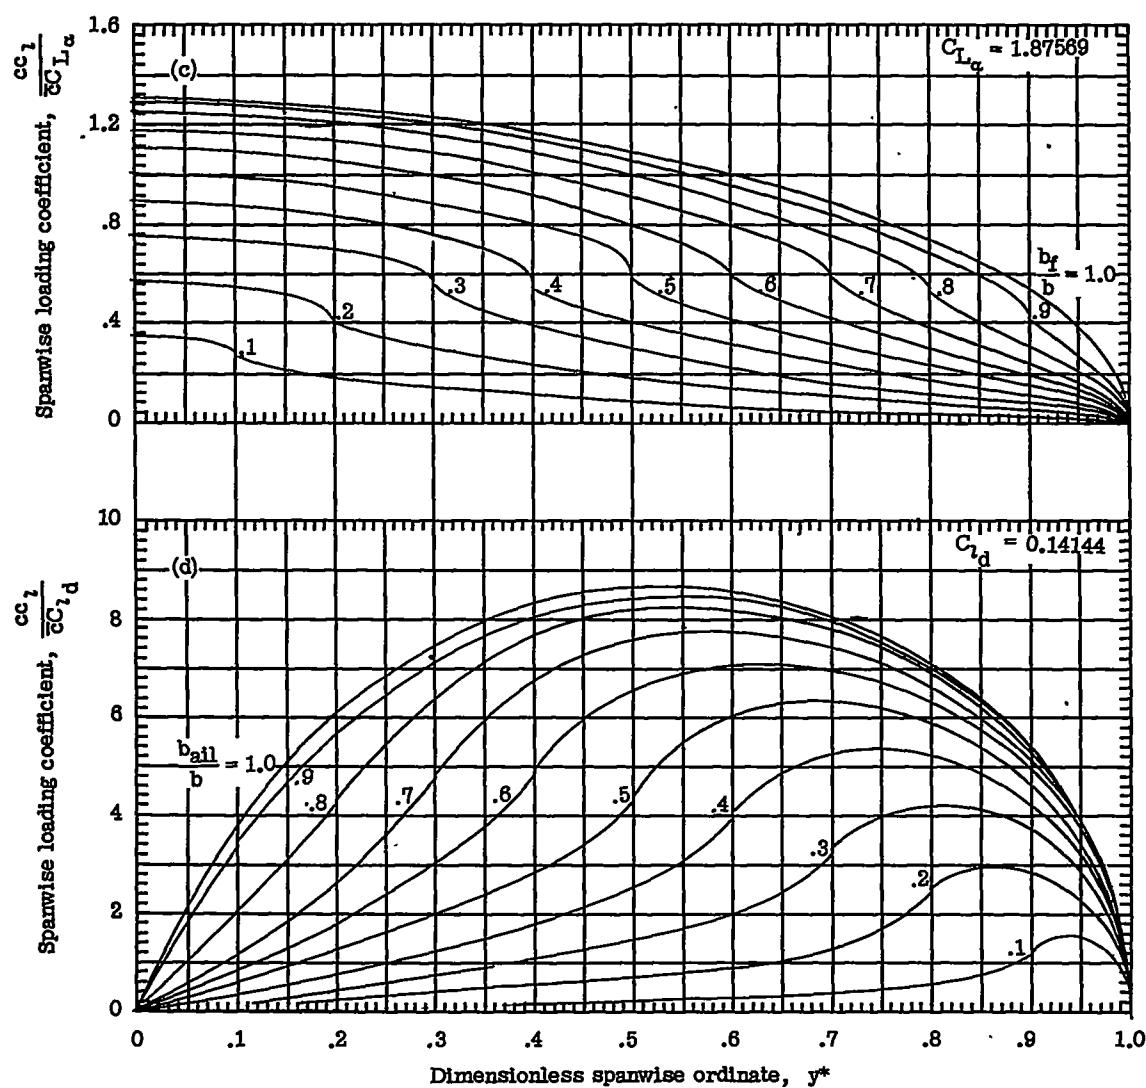

Figure 4.- Concluded.

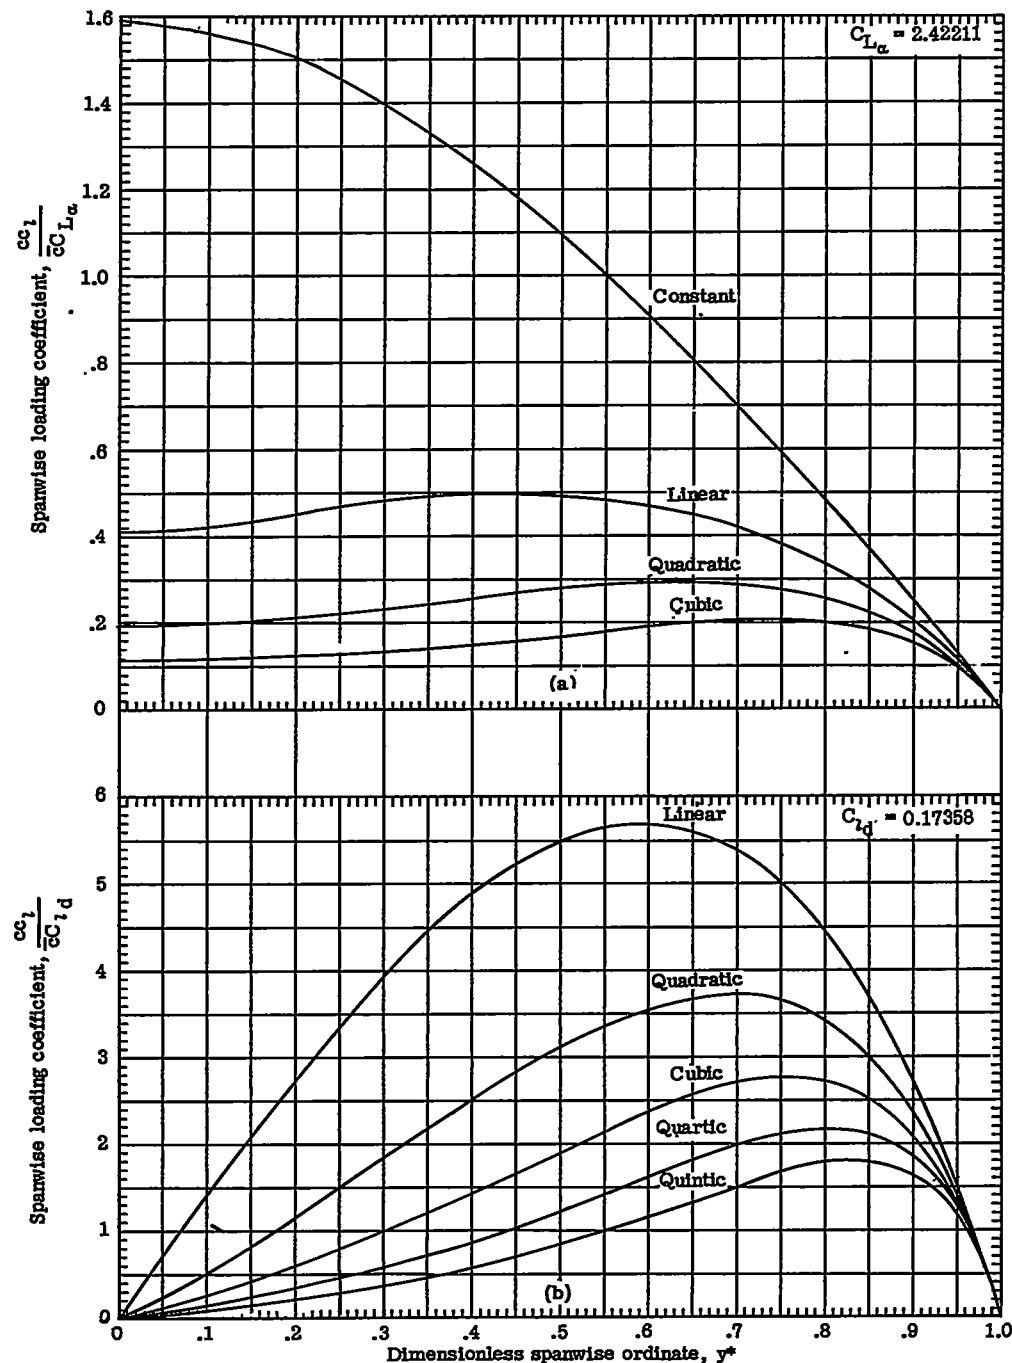

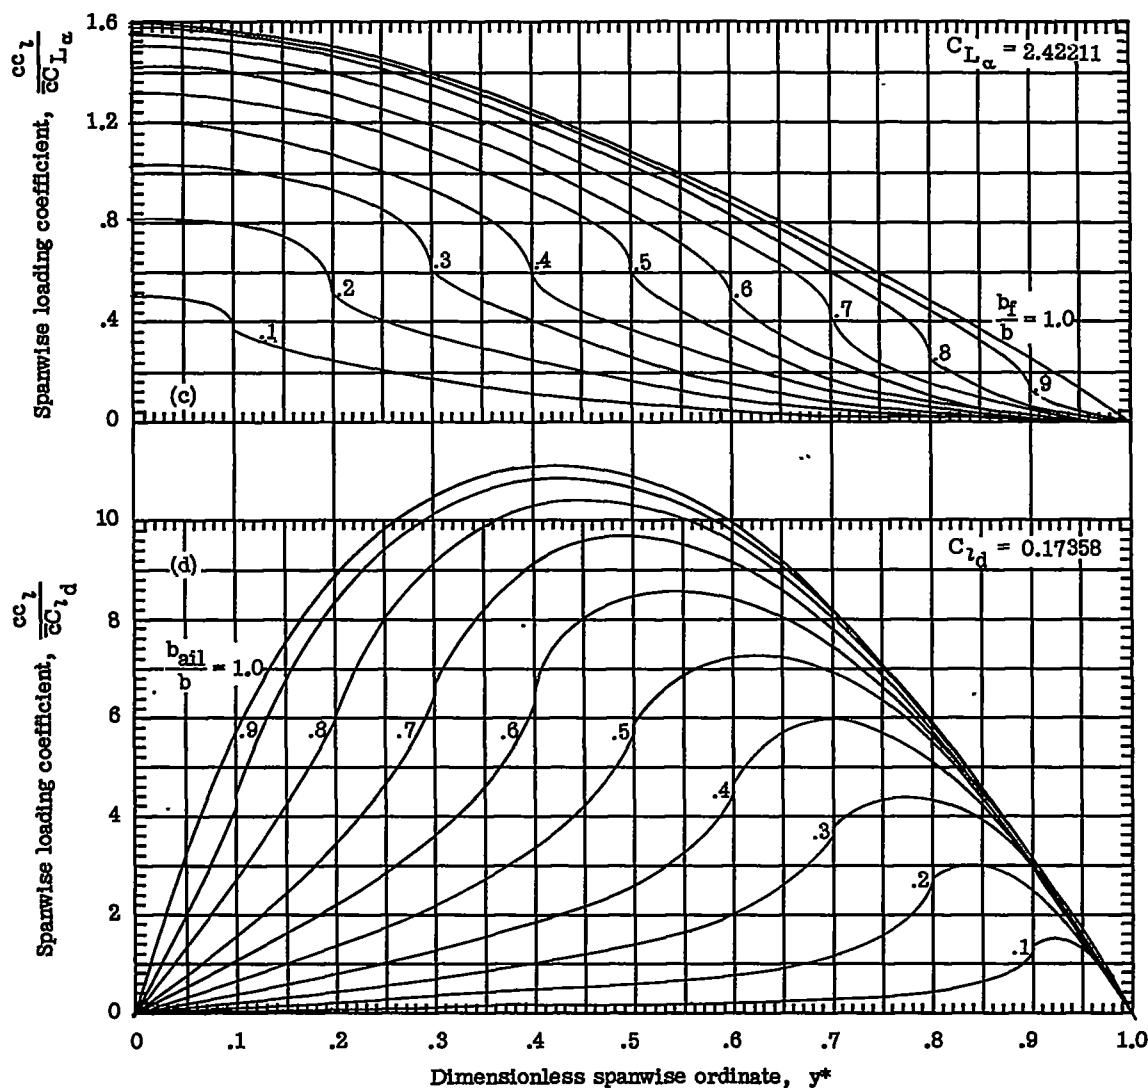

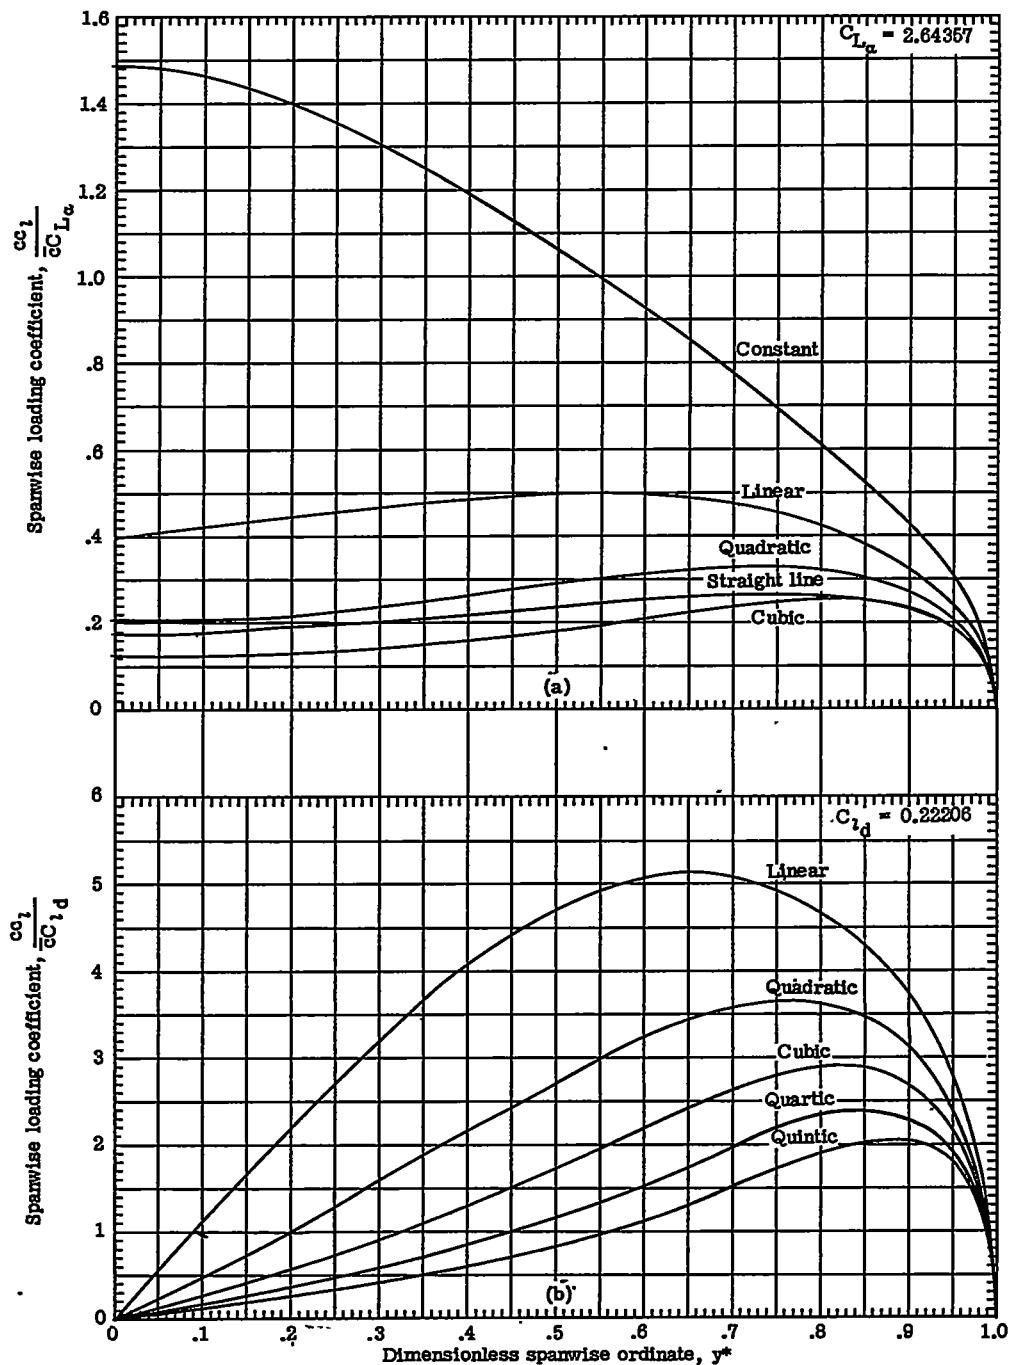

Figure 5.- Spanwise lift distributions for plan form 121 ($A = 3.0$; $\lambda = 0$; $\Lambda = -45^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

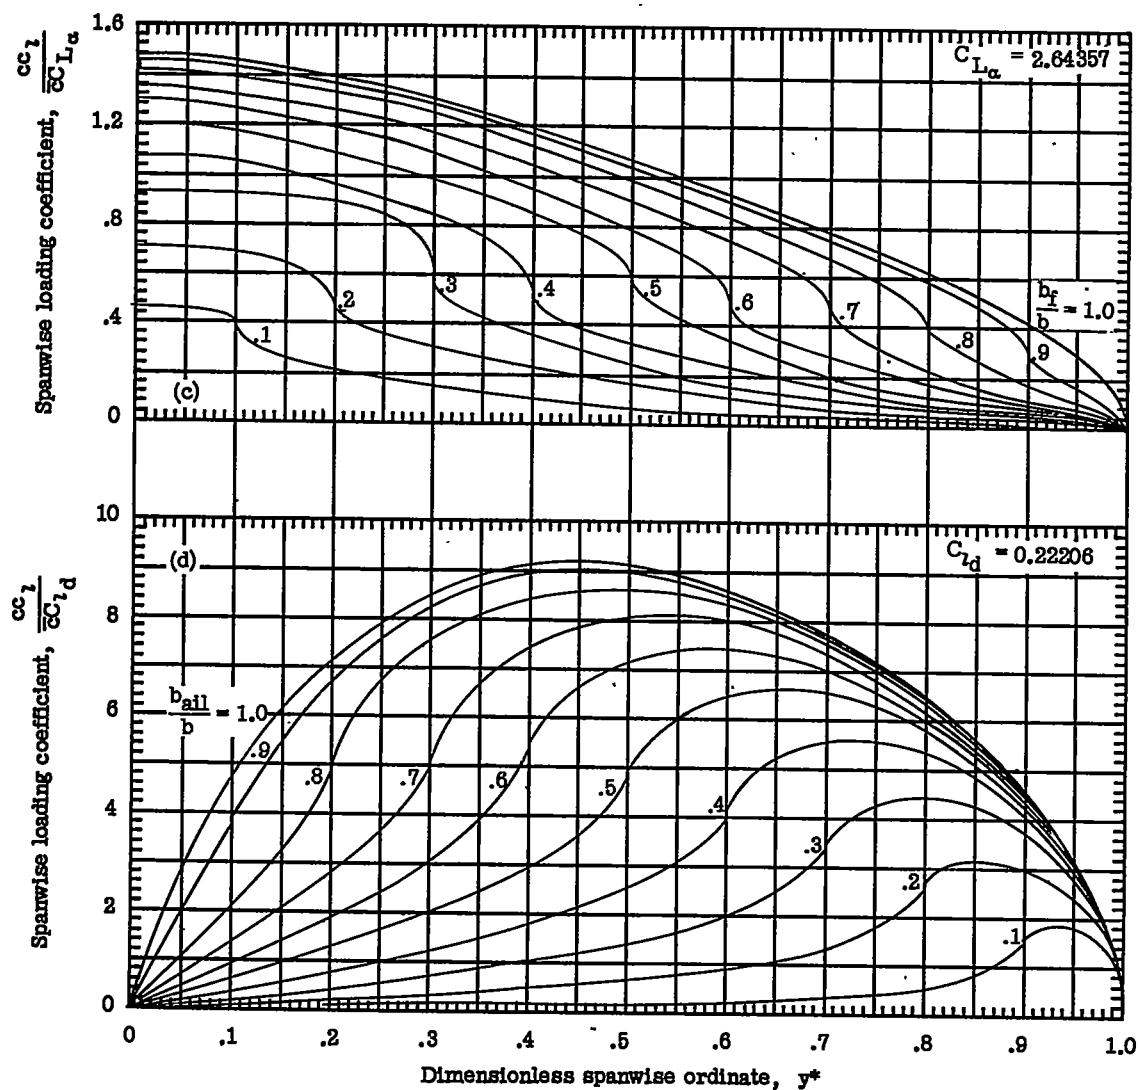

Figure 5.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

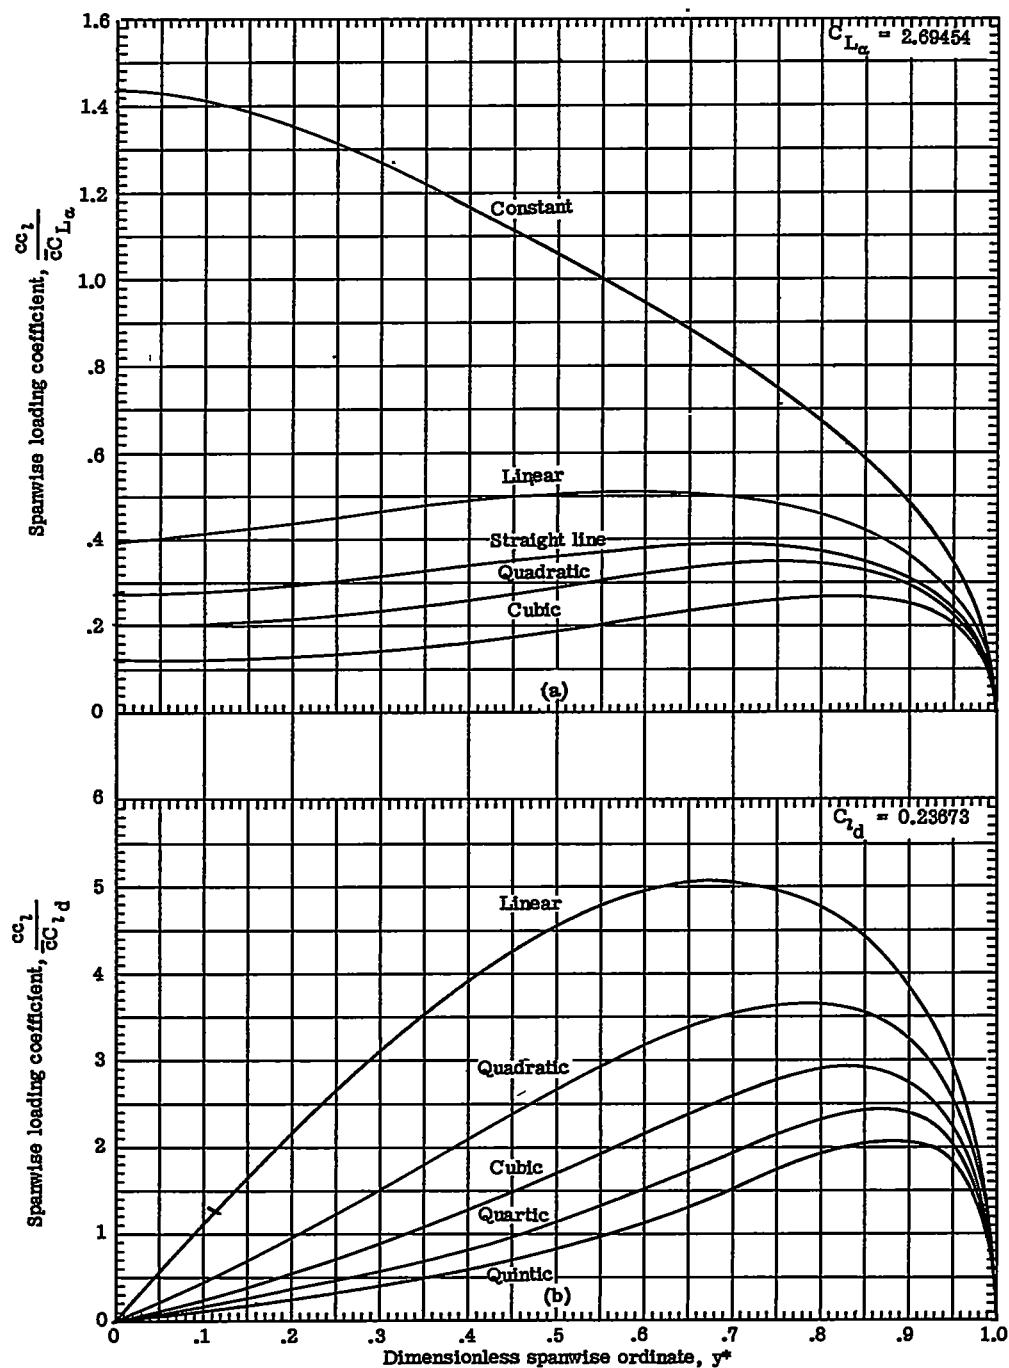

Figure 6.- Spanwise lift distributions for plan form 122 ($A = 3.0$; $\lambda = 0.25$; $\Lambda = -45^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 6.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 7-- Spanwise lift distributions for plan form 123 ($A = 3.0$; $\lambda = 0.50$; $\Lambda = -45^\circ$).

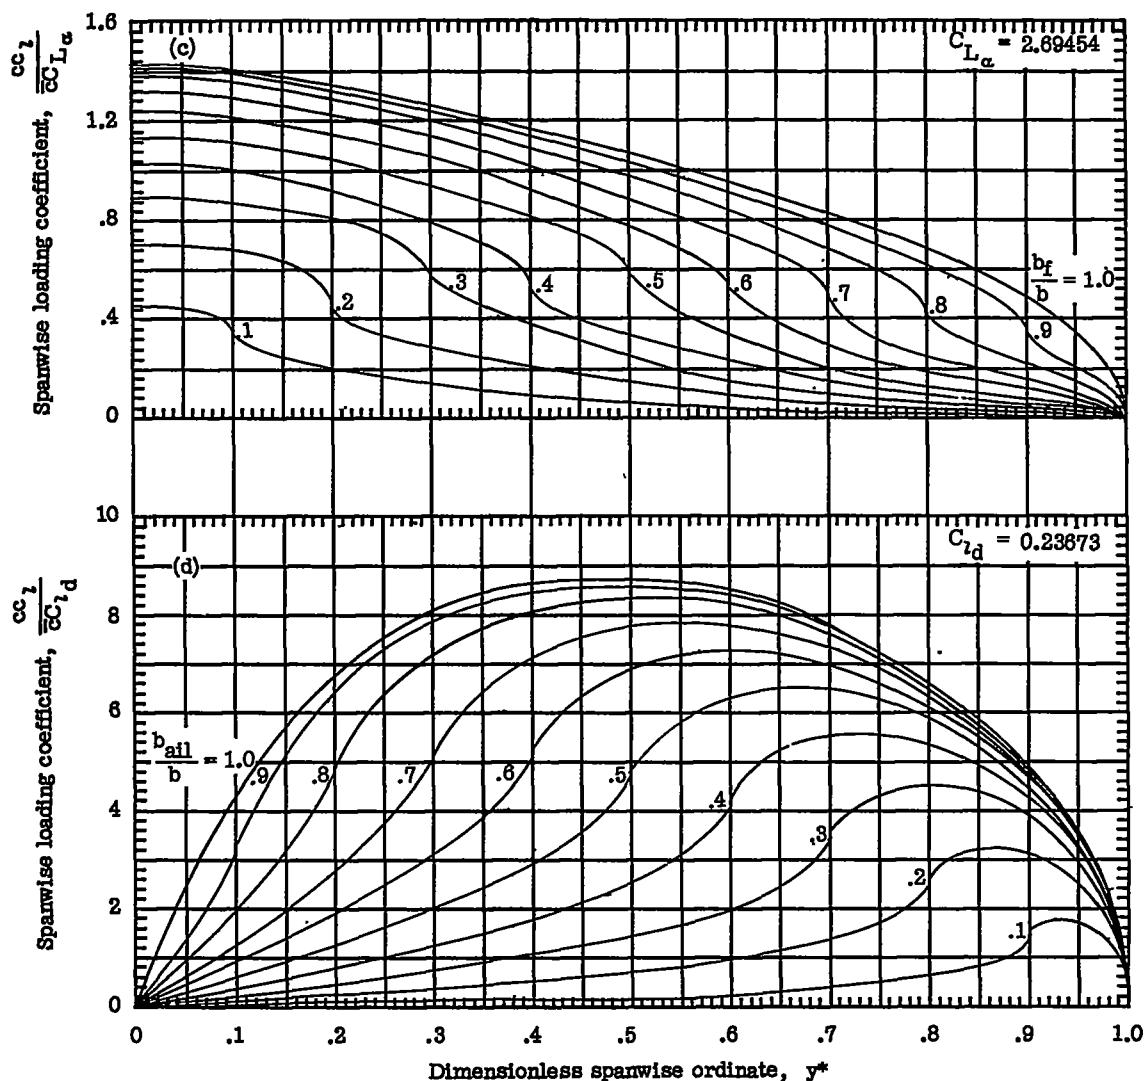

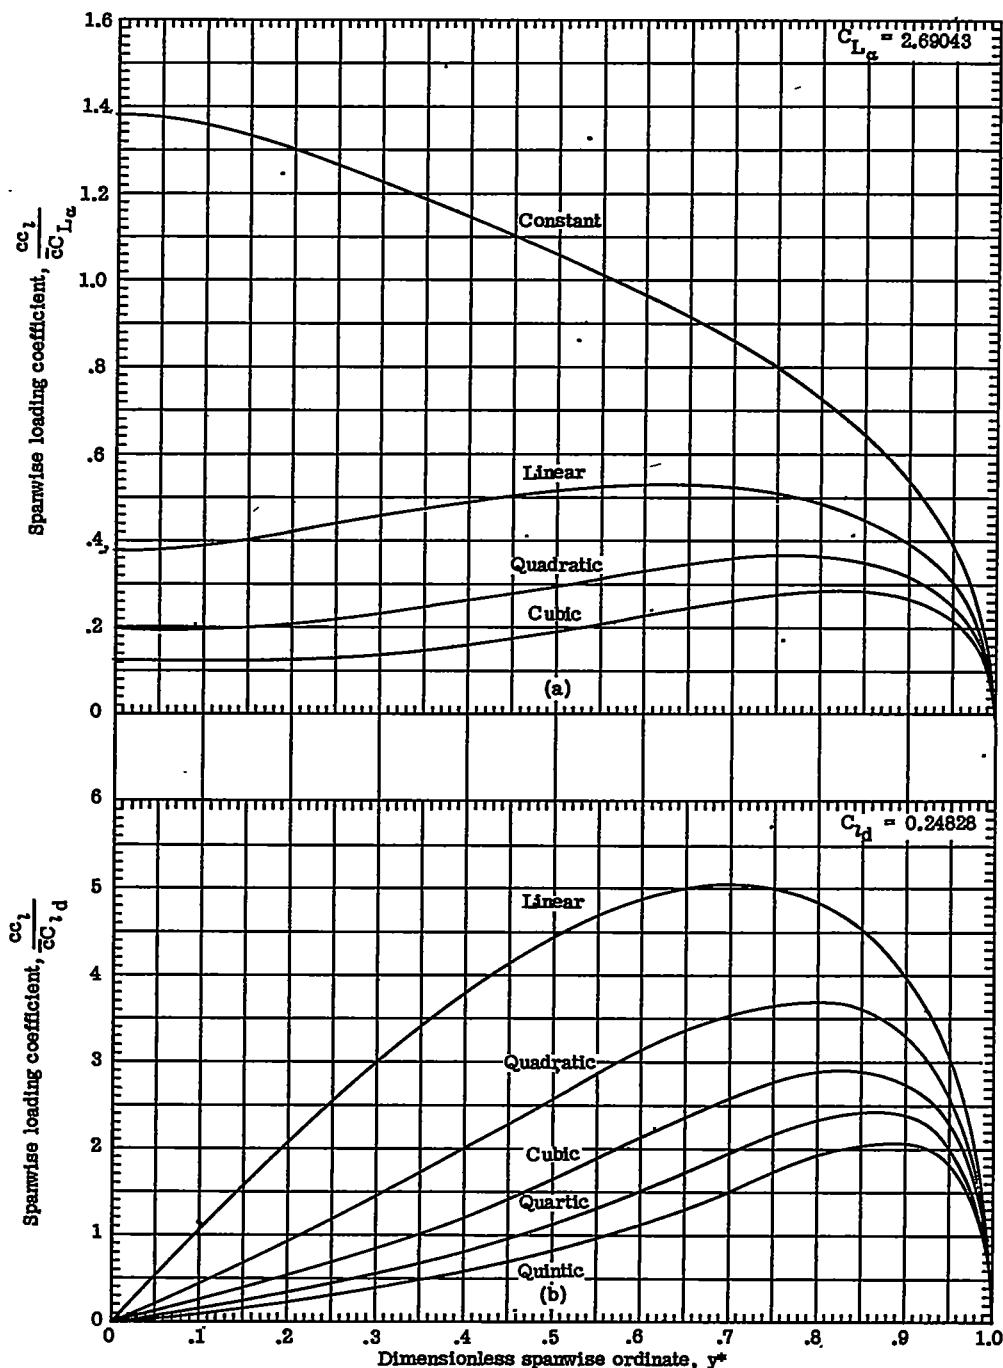

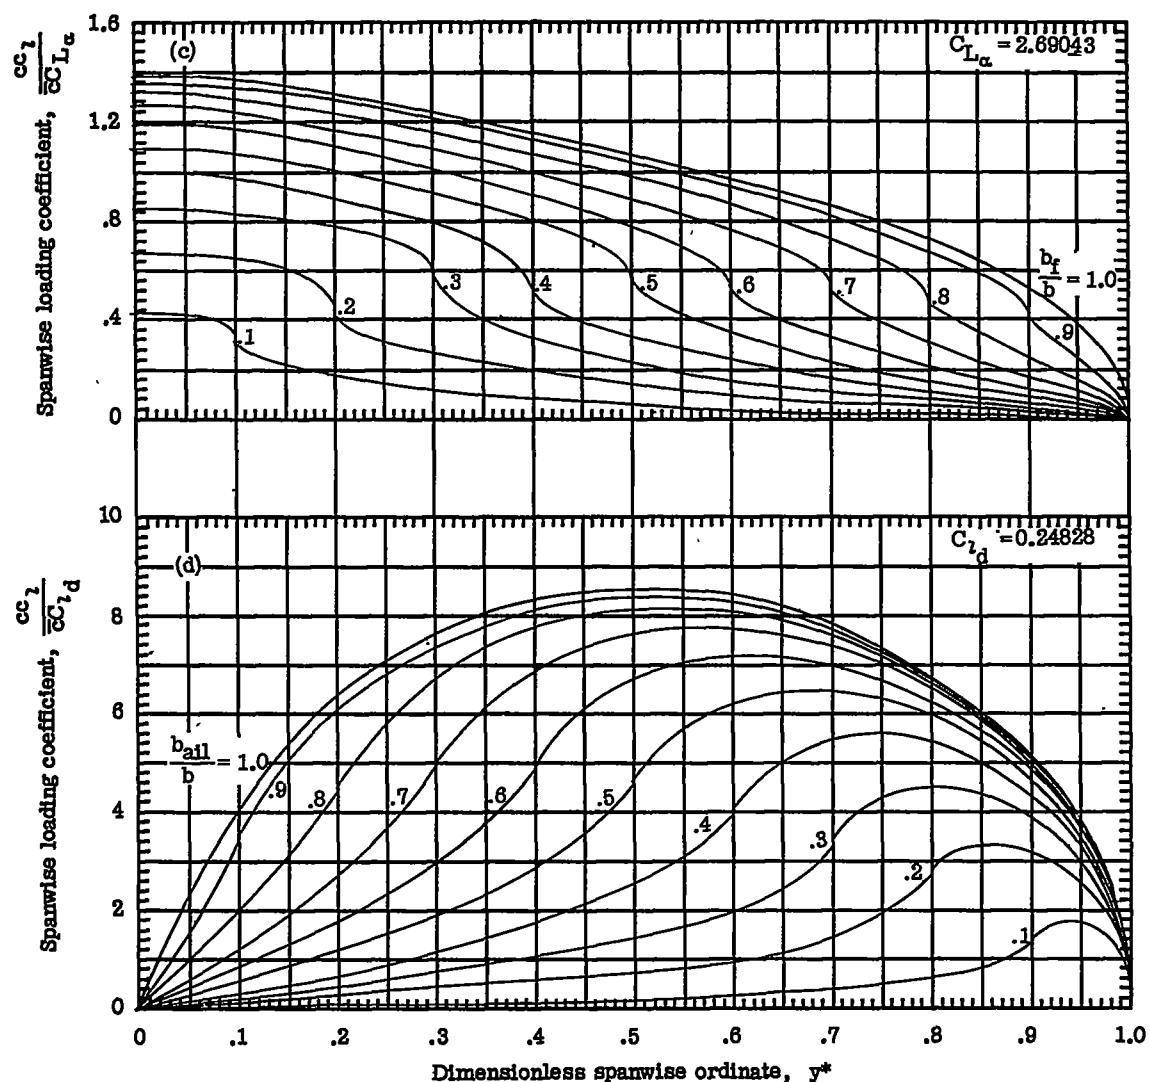

Figure 7:- Concluded.

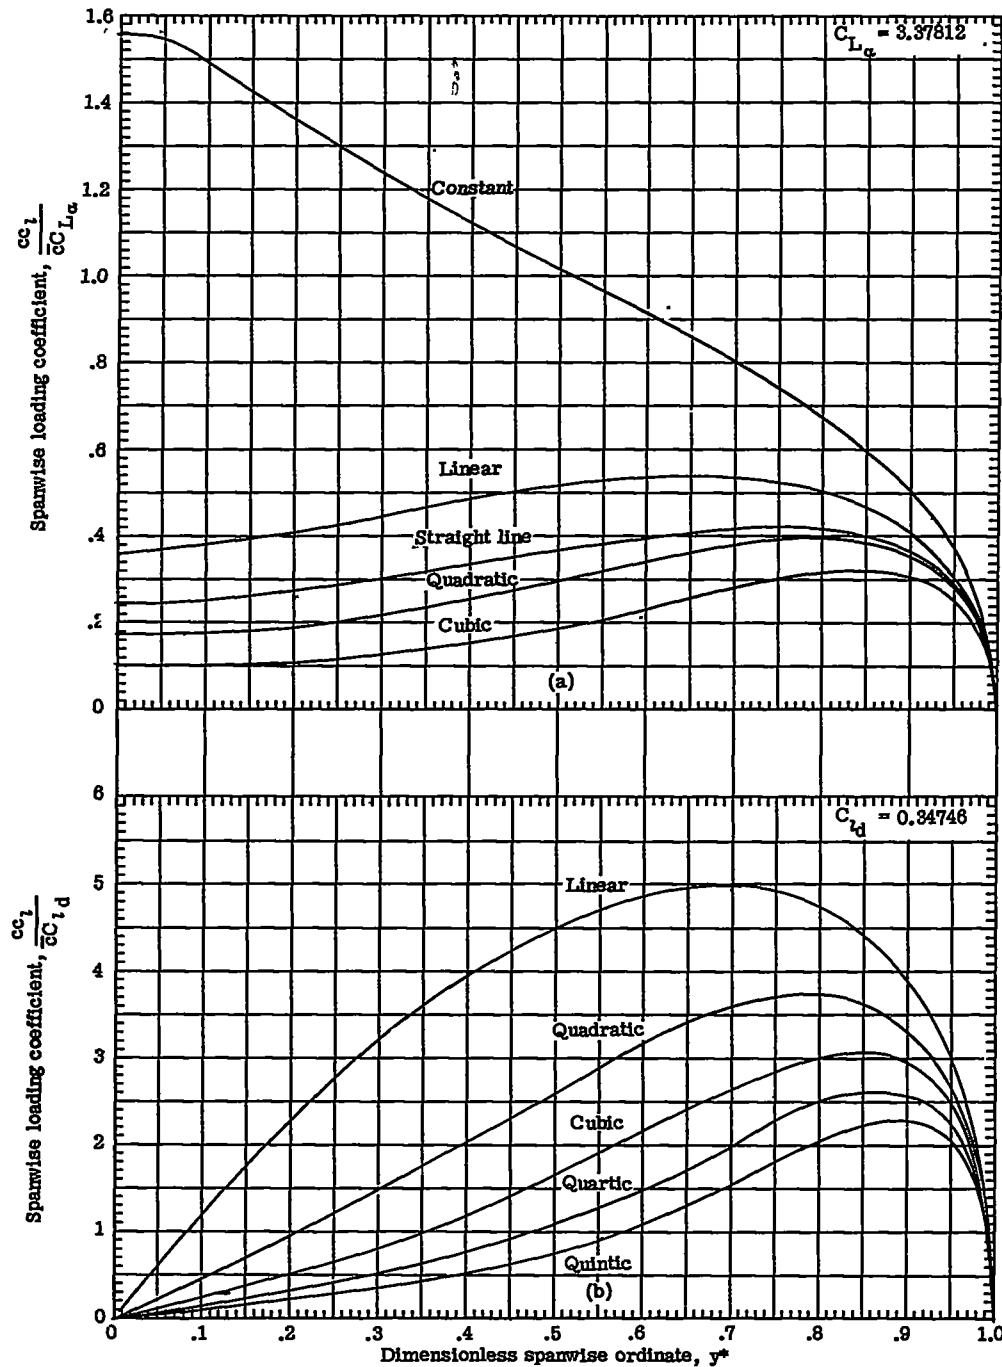

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 8.- Spanwise lift distributions for plan form 124 ($A = 3.0$; $\lambda = 1.00$; $\Lambda = -45^\circ$).

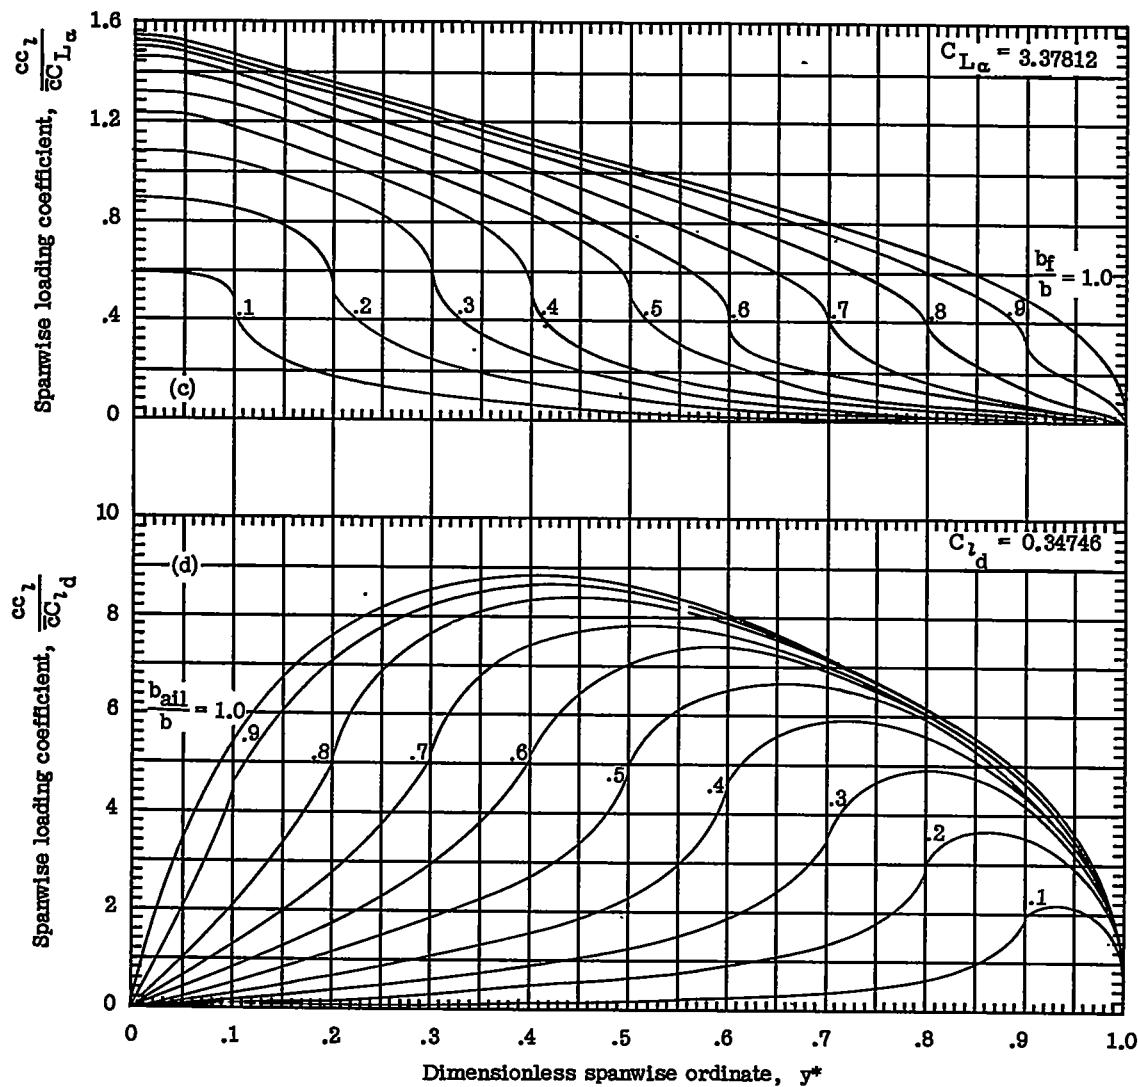

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 9.- Spanwise lift distributions for plan form 133 ($A = 6.0$; $\lambda = 0.50$; $\Lambda \approx -45^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 9.- Concluded.

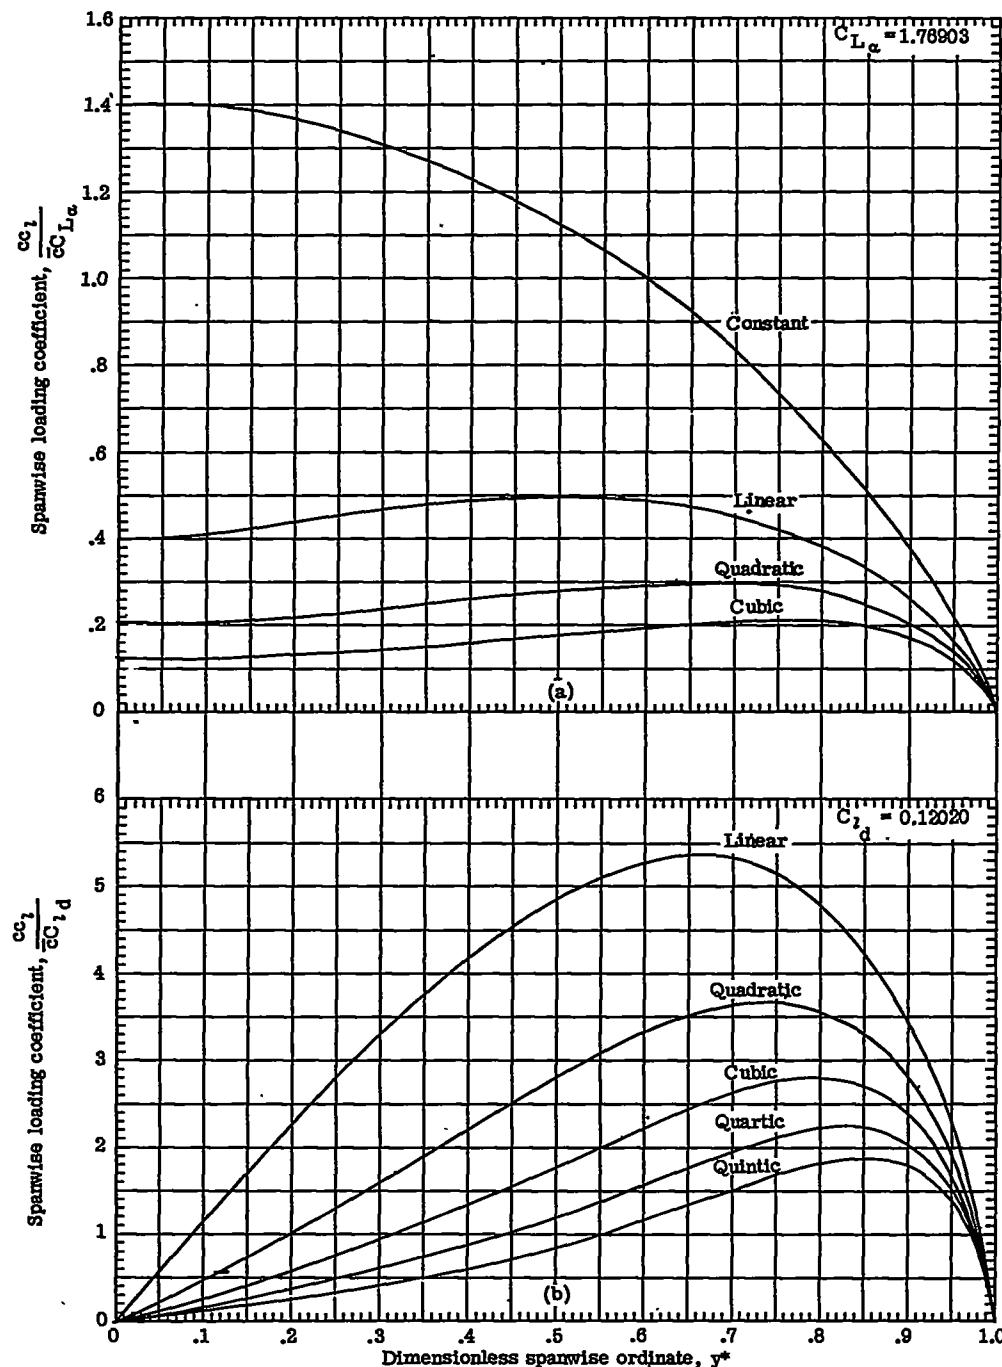

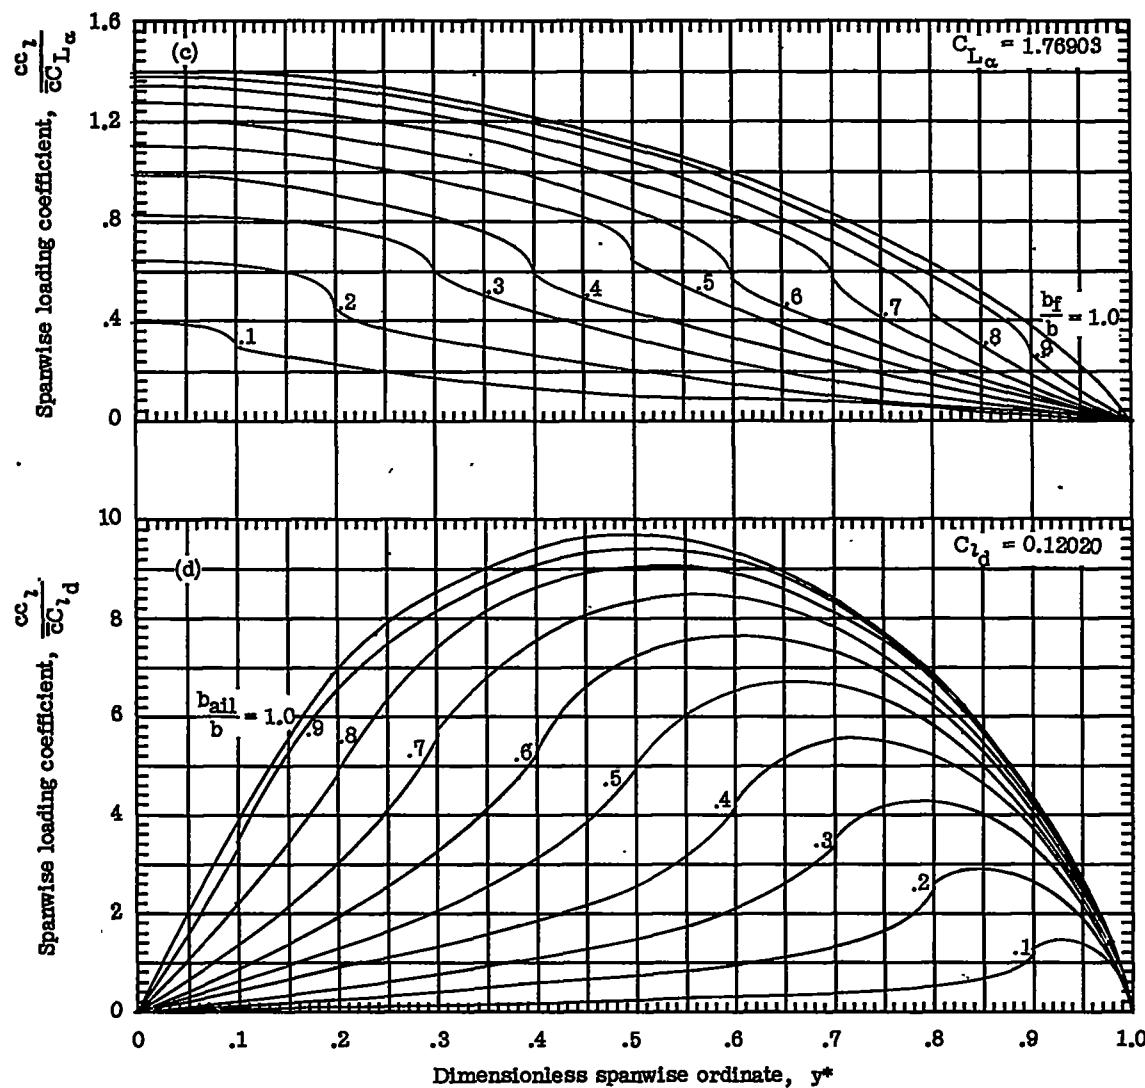

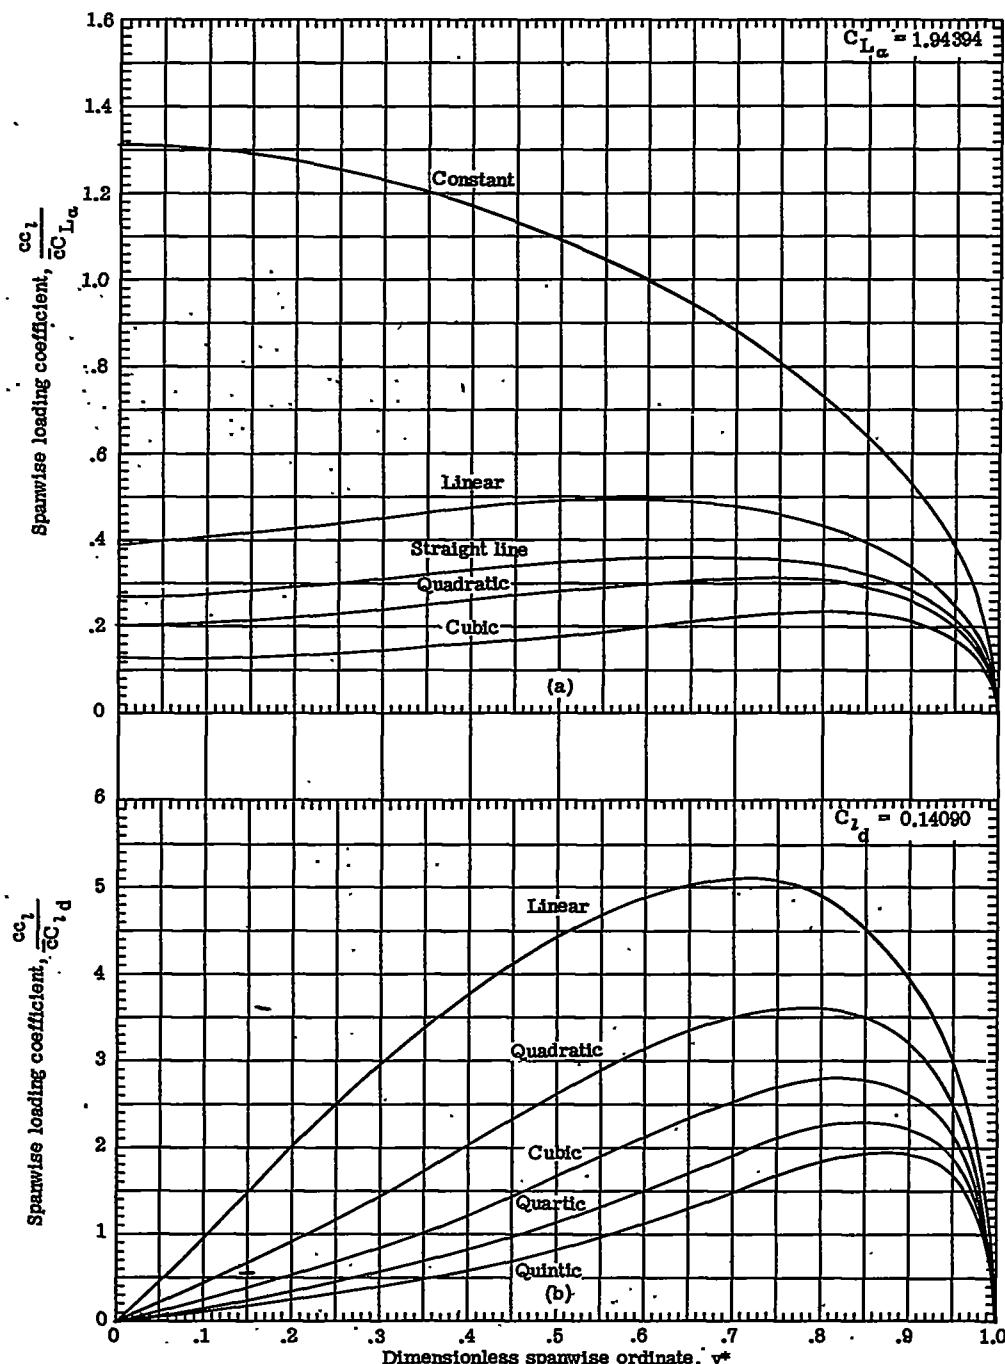

Figure 10.- Spanwise lift distributions for plan form 211 ($A = 1.5$; $\lambda = 0$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 10.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 11.- Spanwise lift distributions for plan form 213 ($A = 1.5$; $\lambda = 0.50$; $\Lambda = -30^\circ$).

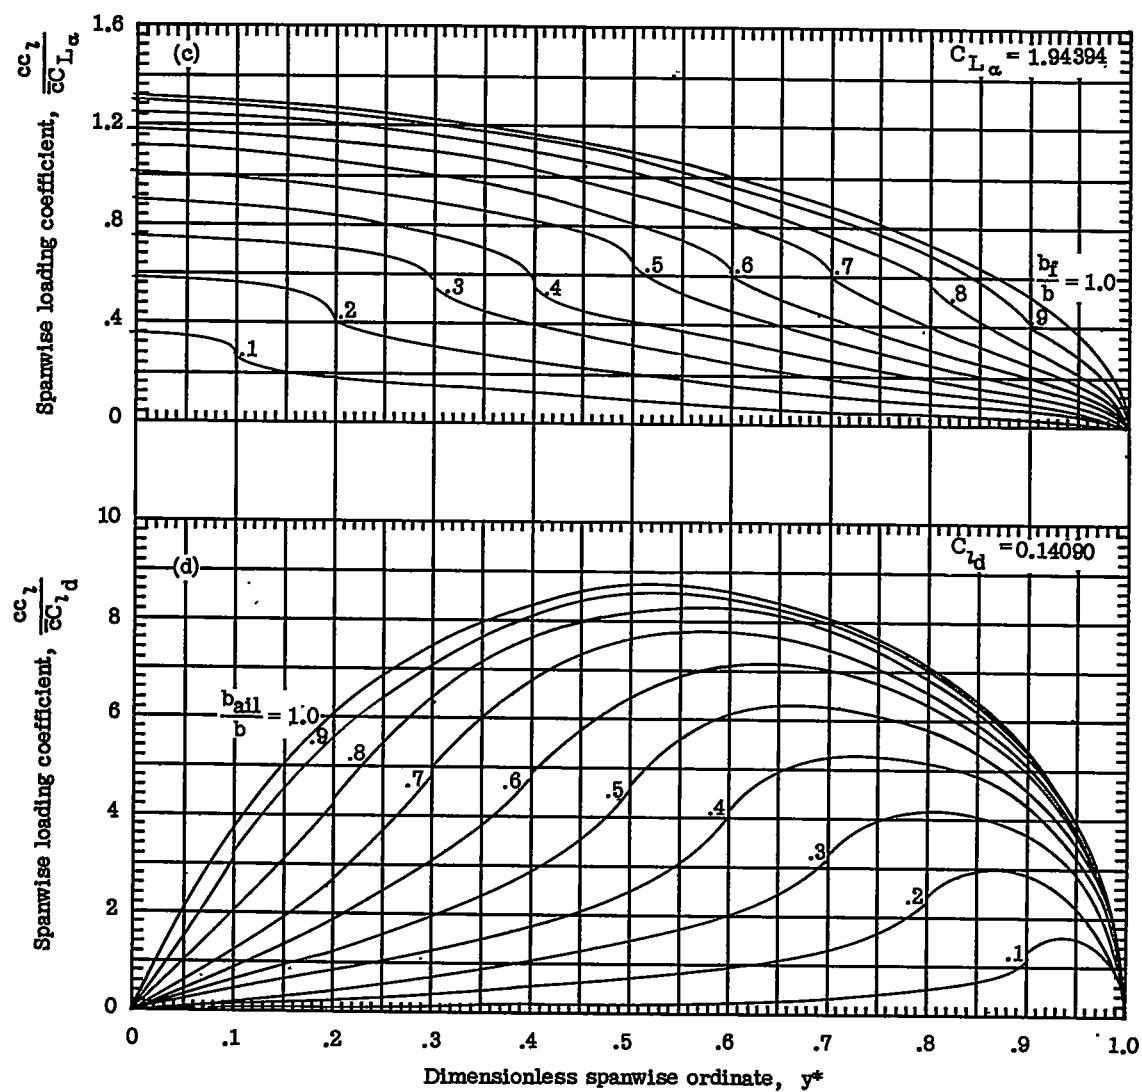

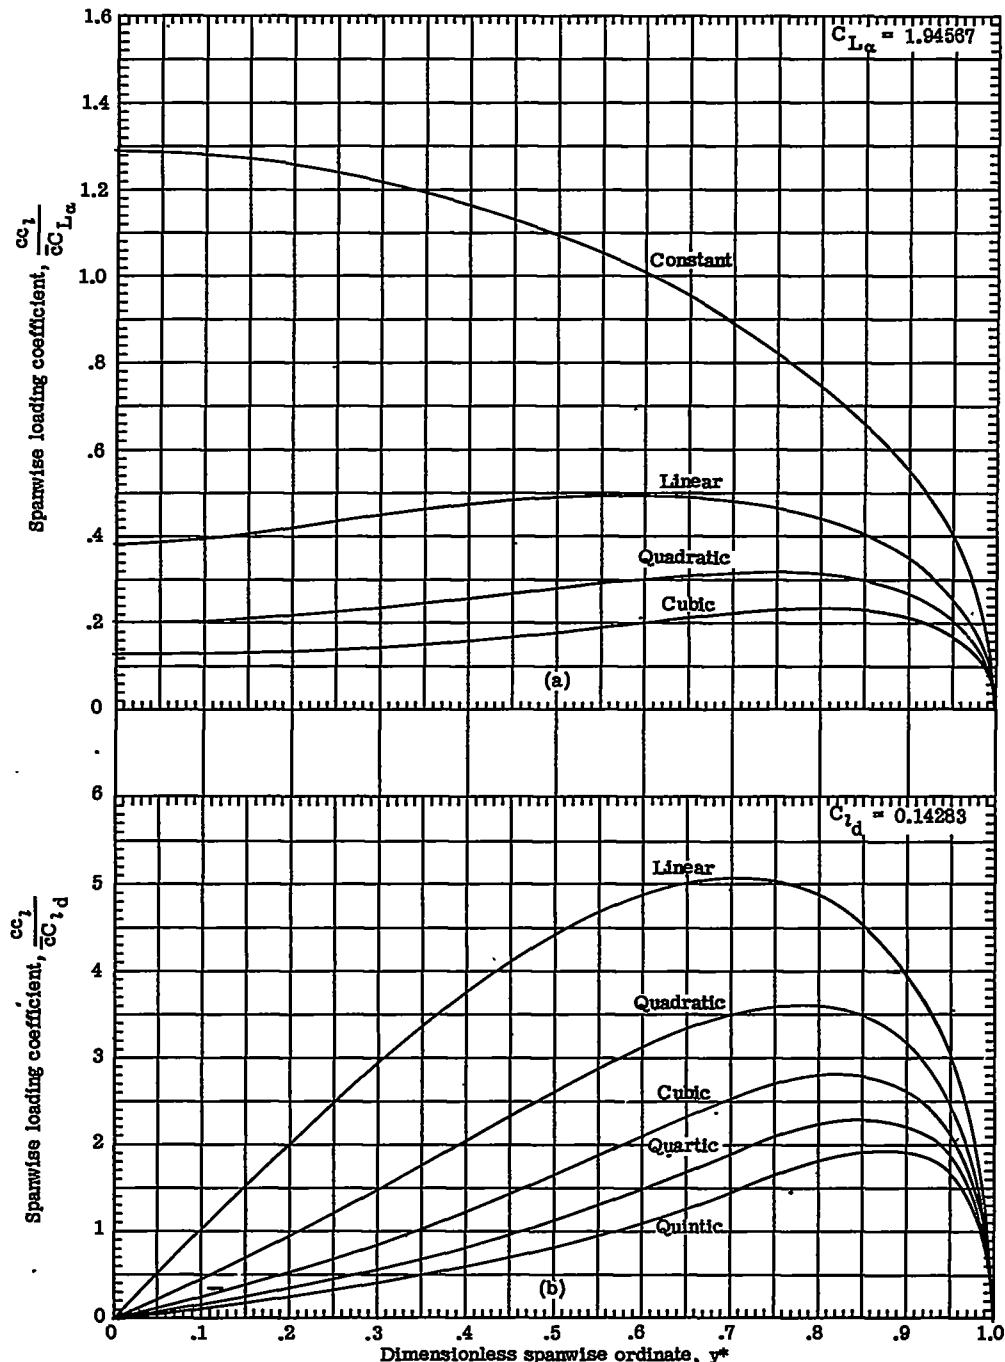

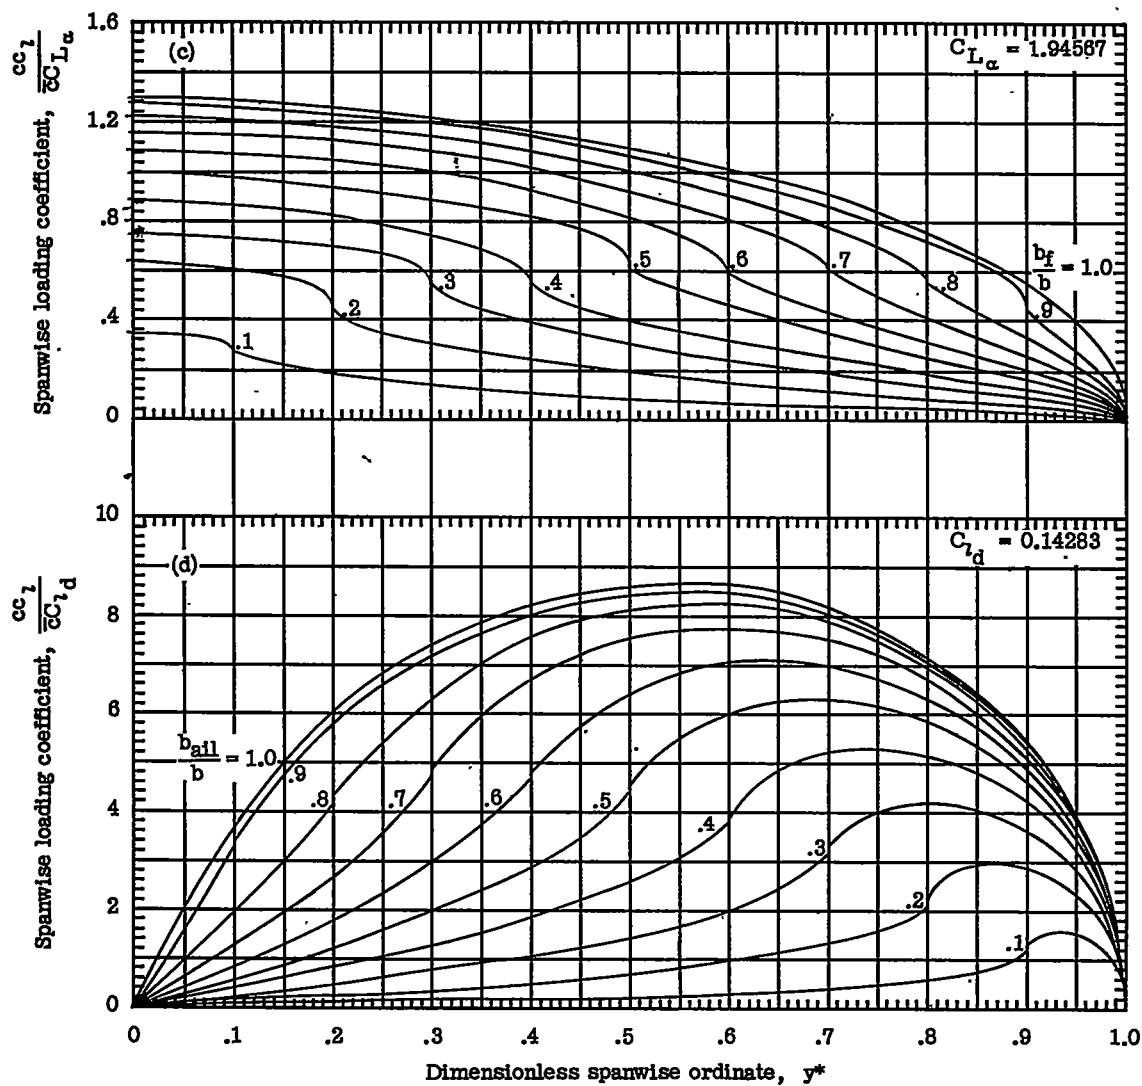

Figure 11.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

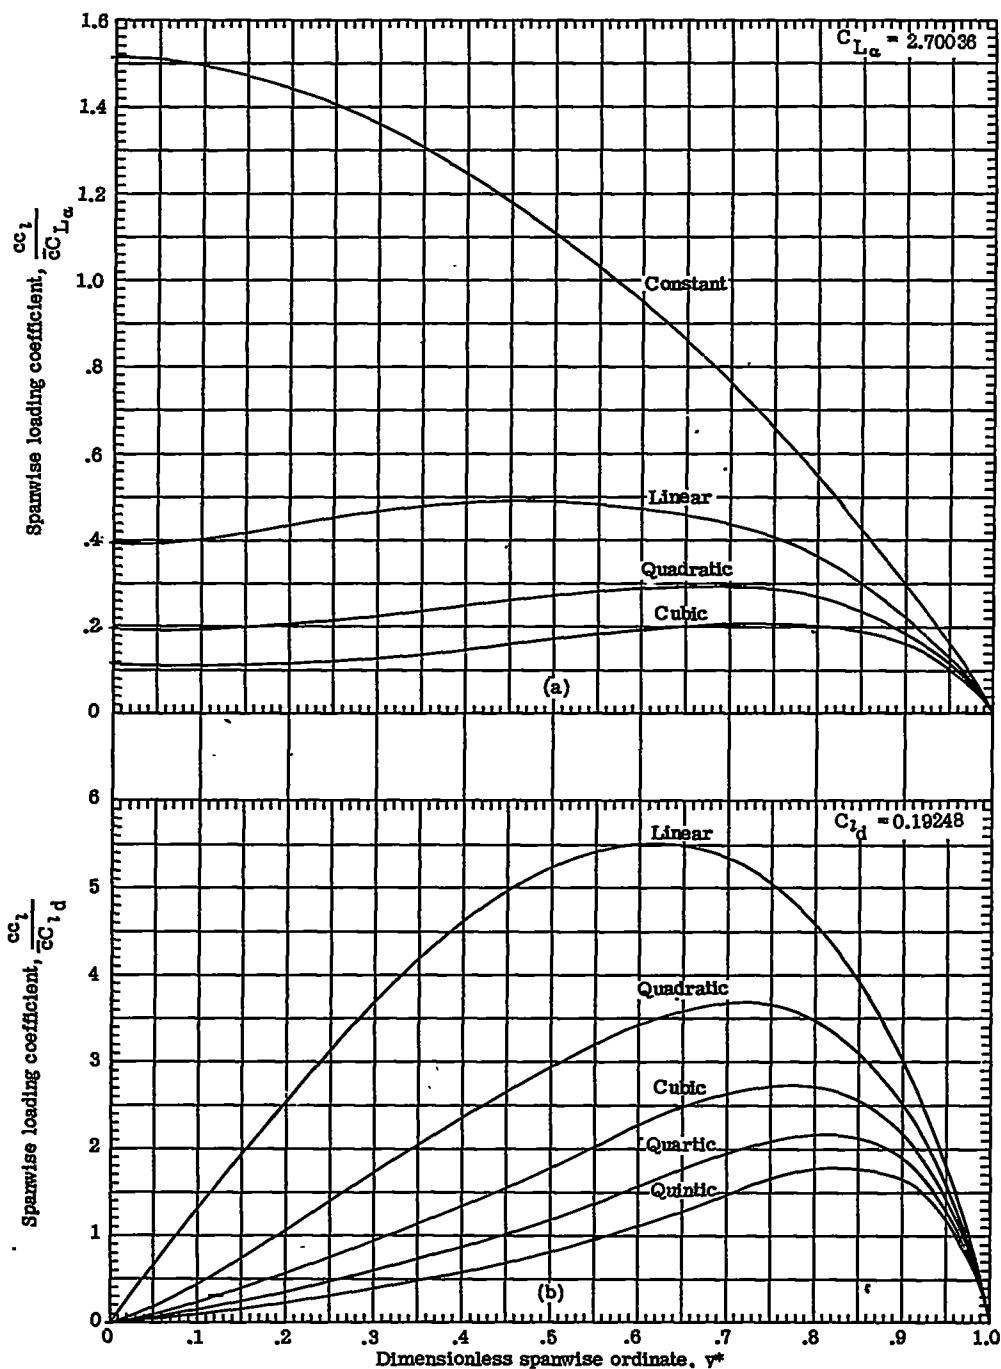

Figure 12.- Spanwise lift distributions for plan form 214 ($A = 1.5$; $\lambda = 1.00$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

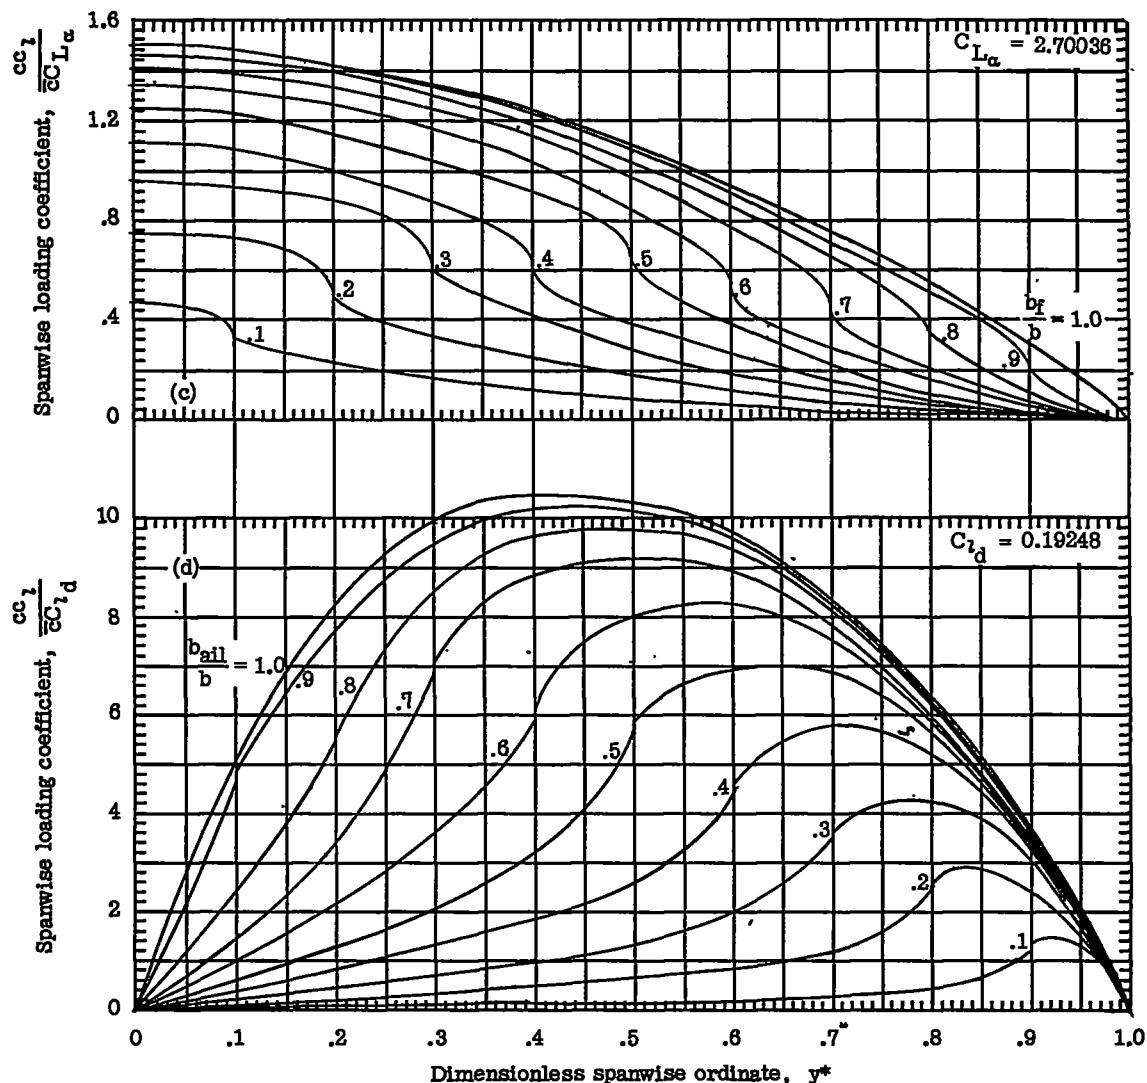

Figure 12.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

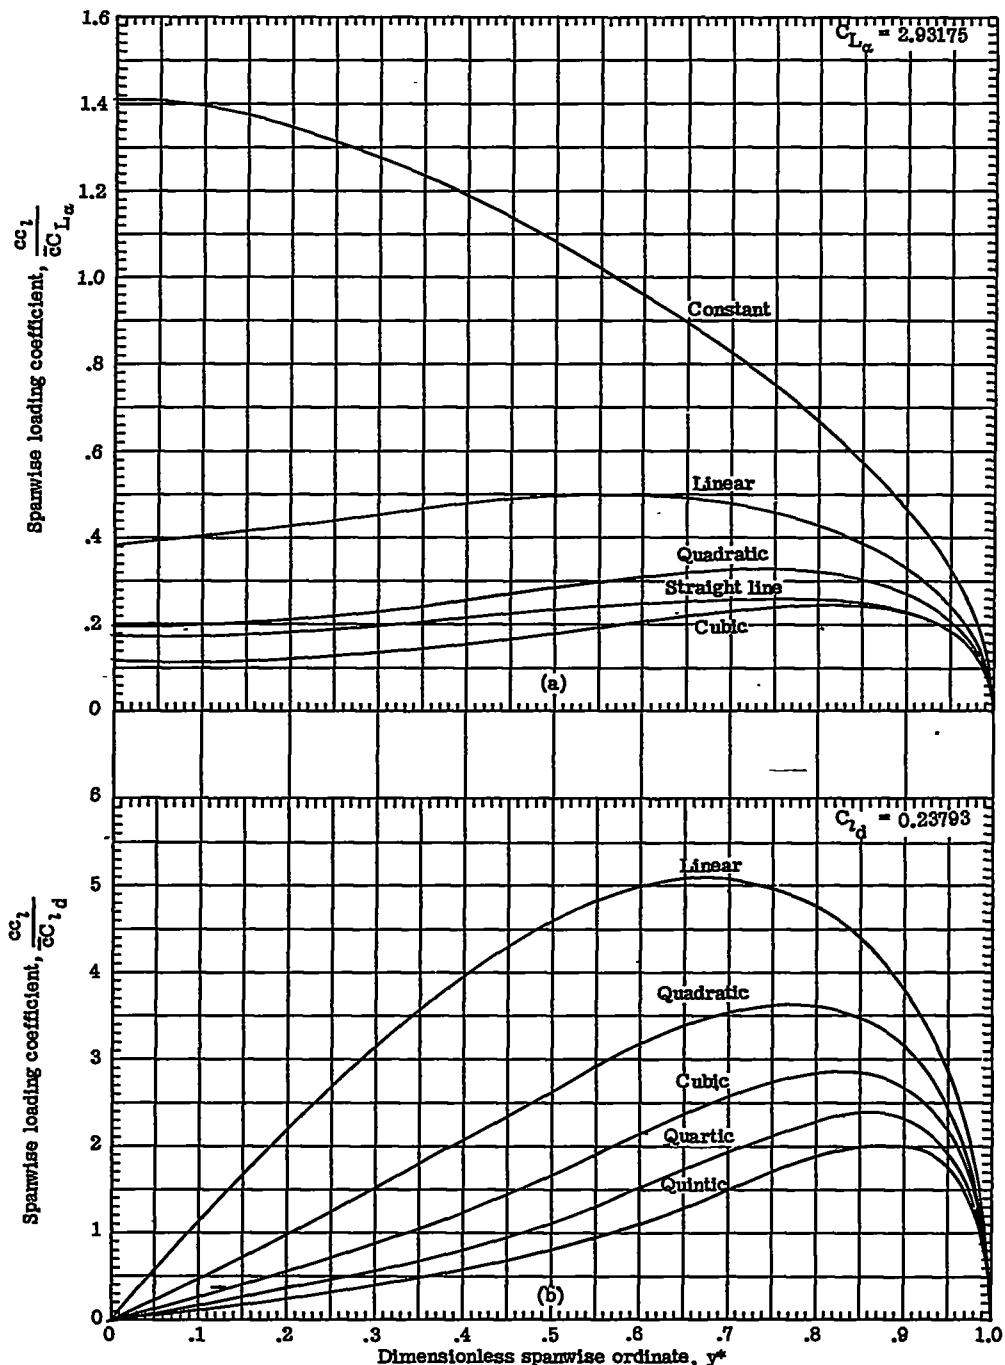

Figure 13.-- Spanwise lift distributions for plan form 221 ($A = 30$;
 $\lambda = 0$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 13.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 14.- Spanwise lift distributions for plan form 222 ($A = 3.0$;
 $\lambda = 0.25$; $\Lambda = -30^\circ$).

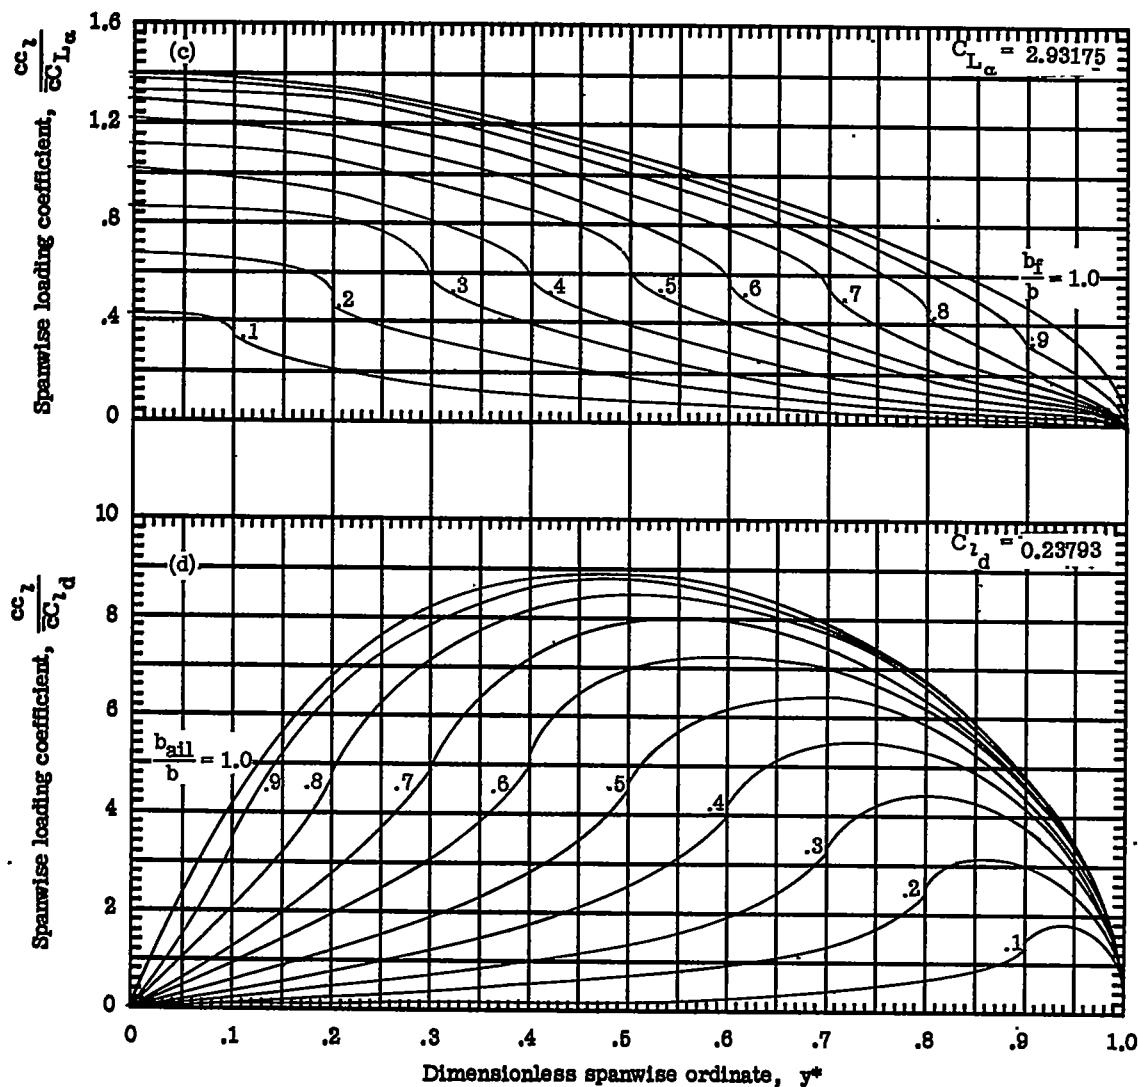

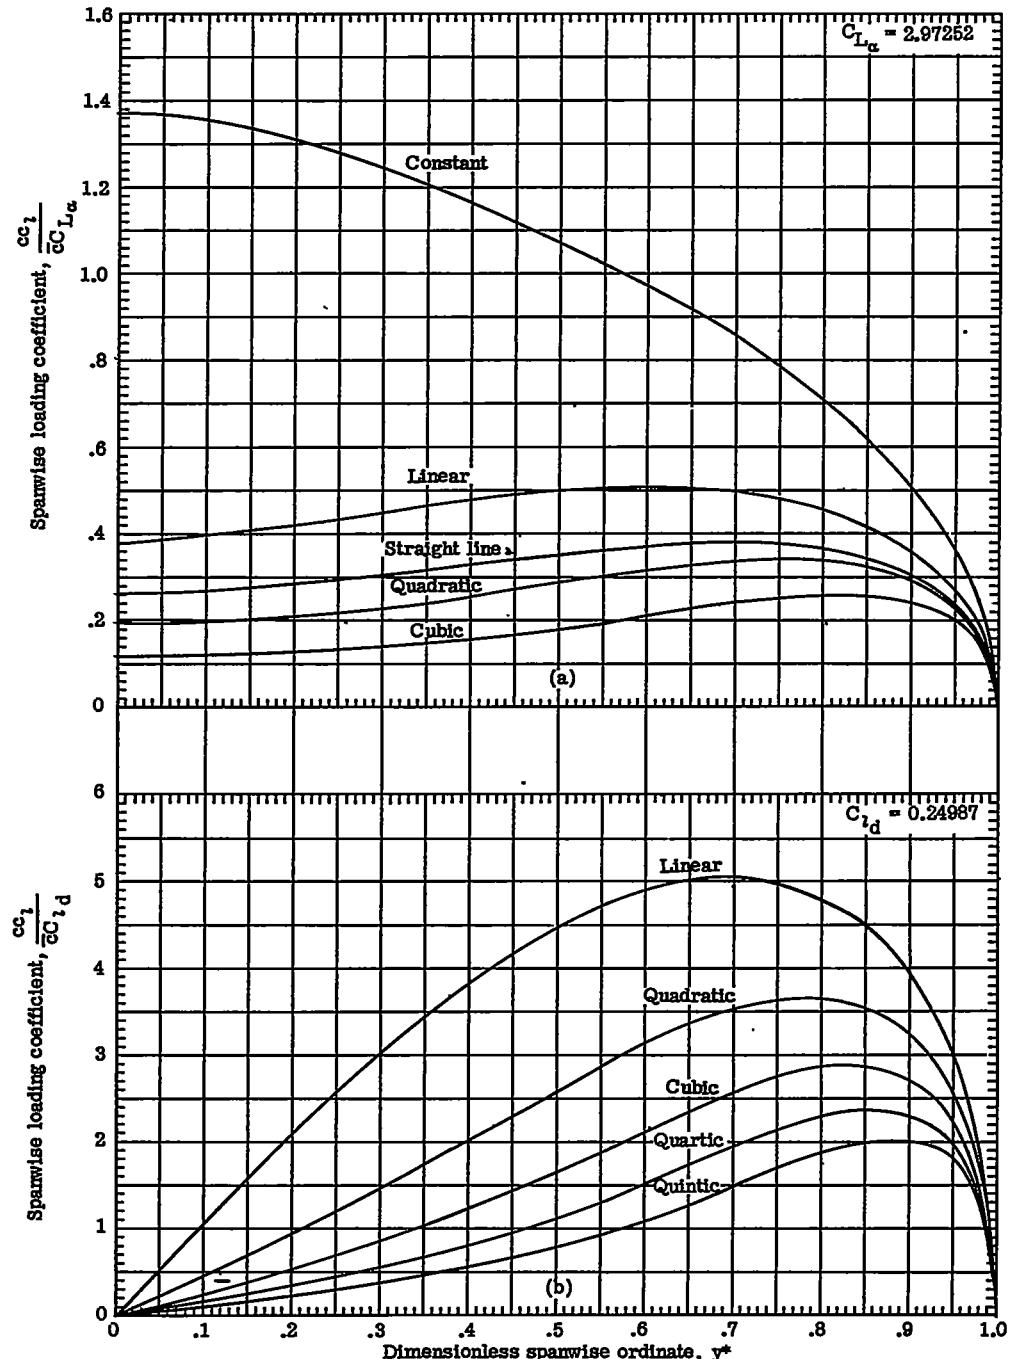

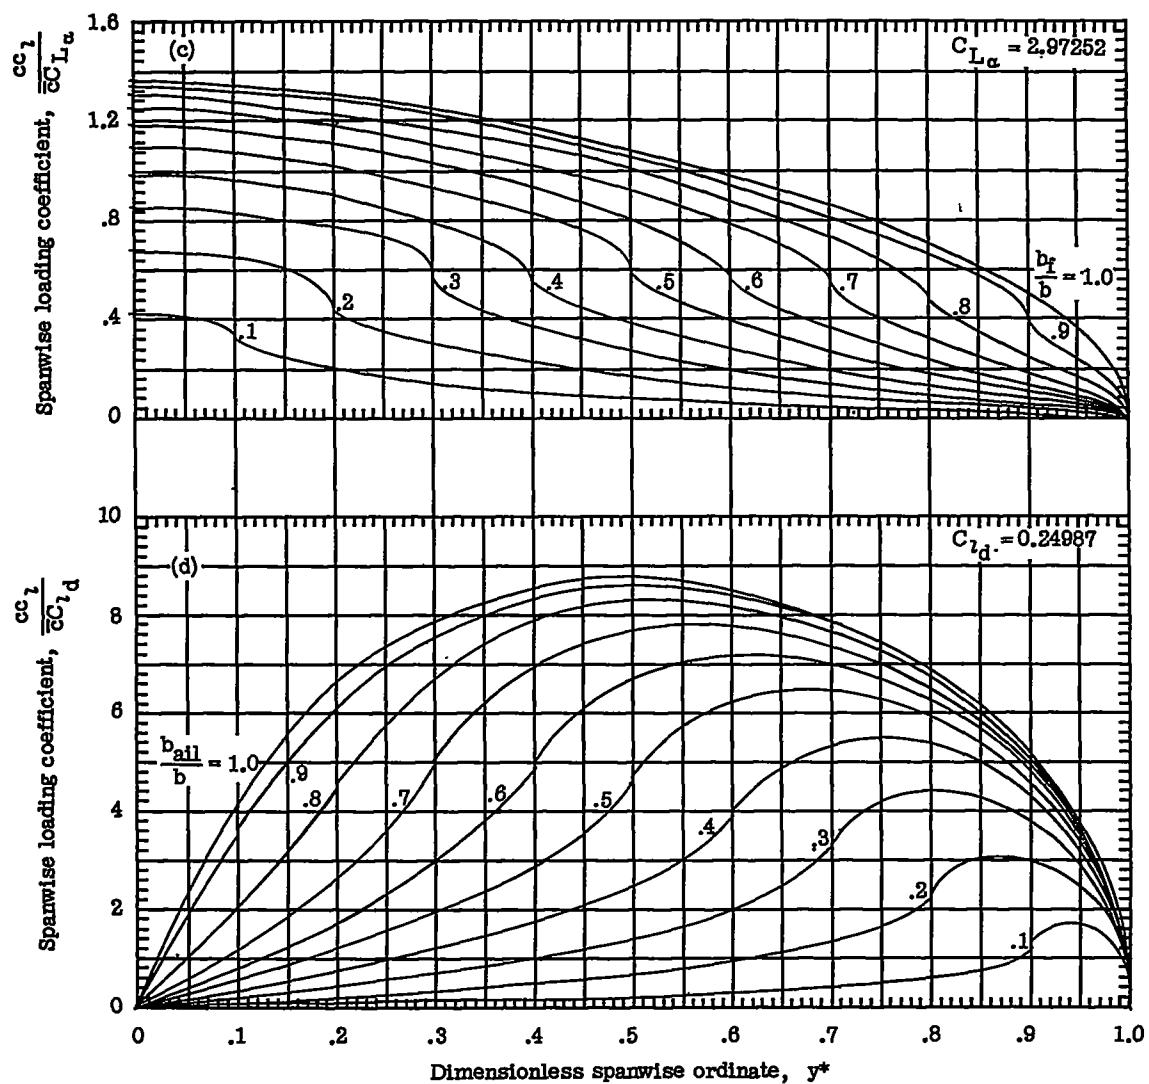

Figure 14.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

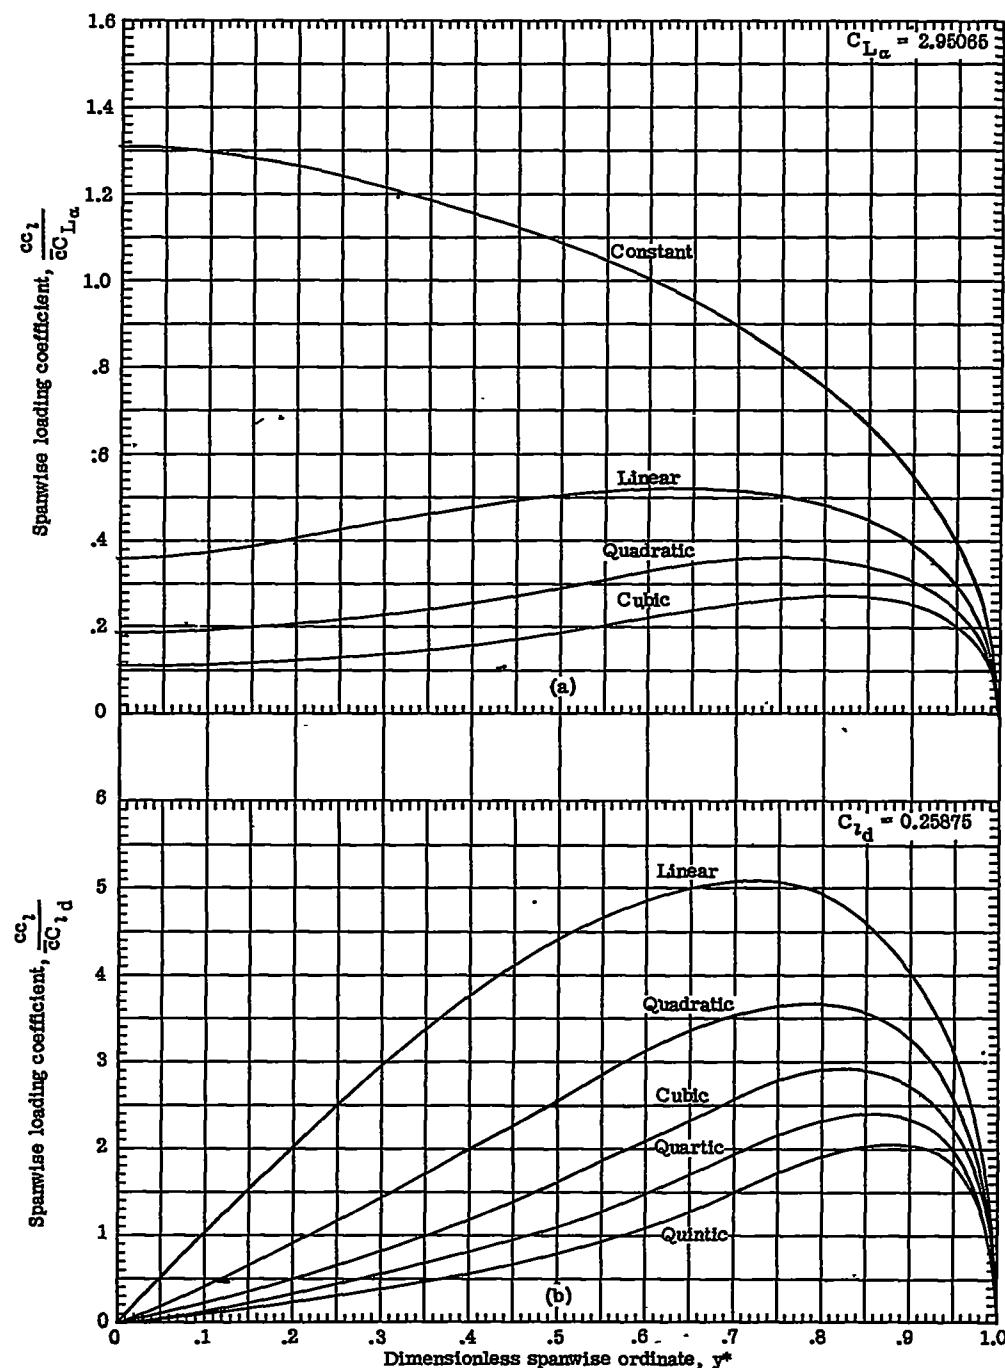

Figure 15.- Spanwise lift distributions for plan form 223 ($A = 3.0$; $\lambda = 0.50$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 15.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 16.- Spanwise lift distributions for plan form 224 ($A = 3.0$;
 $\lambda = 1.00$; $\Lambda = -30^\circ$).

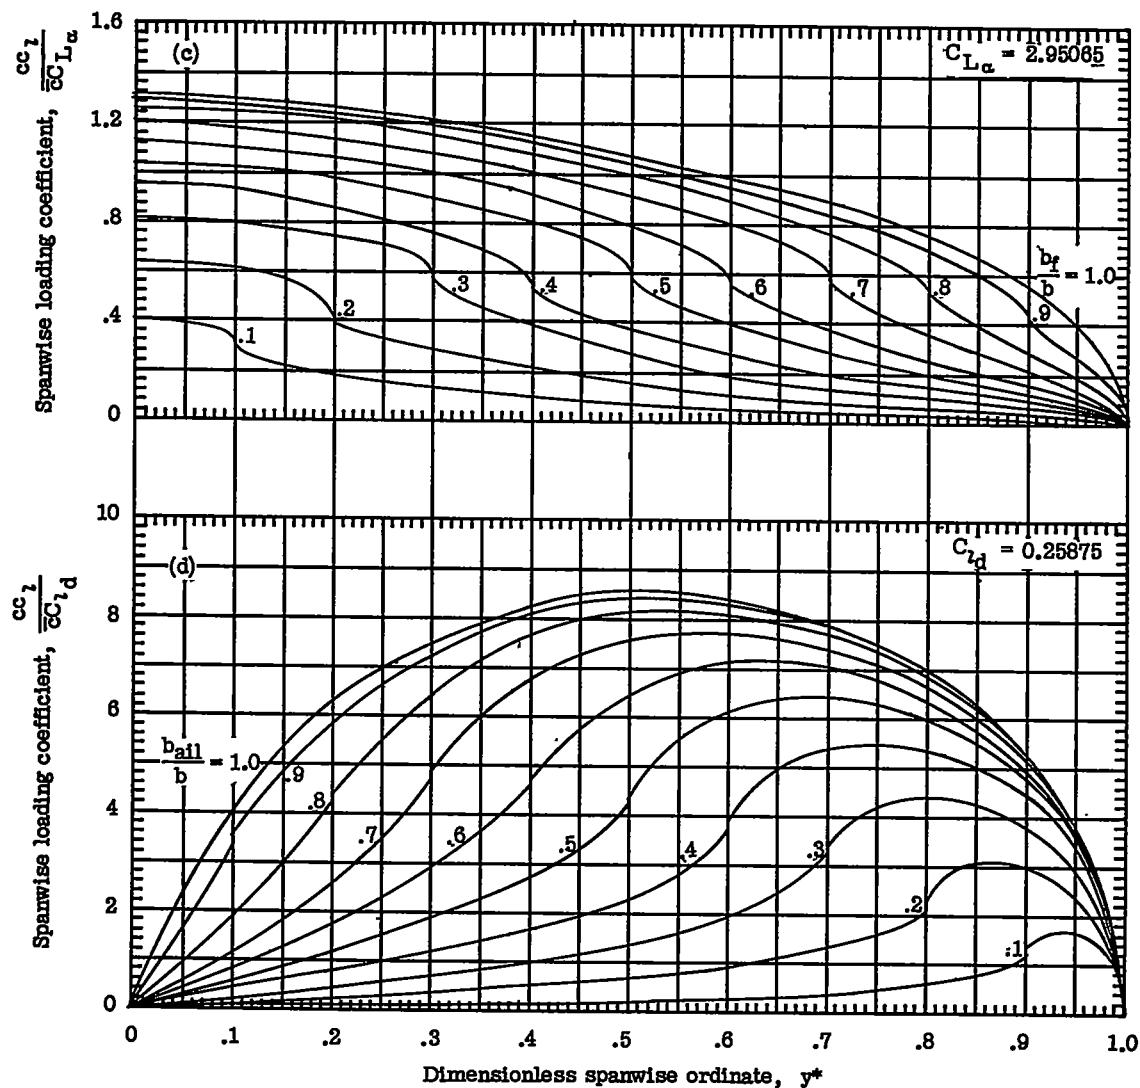

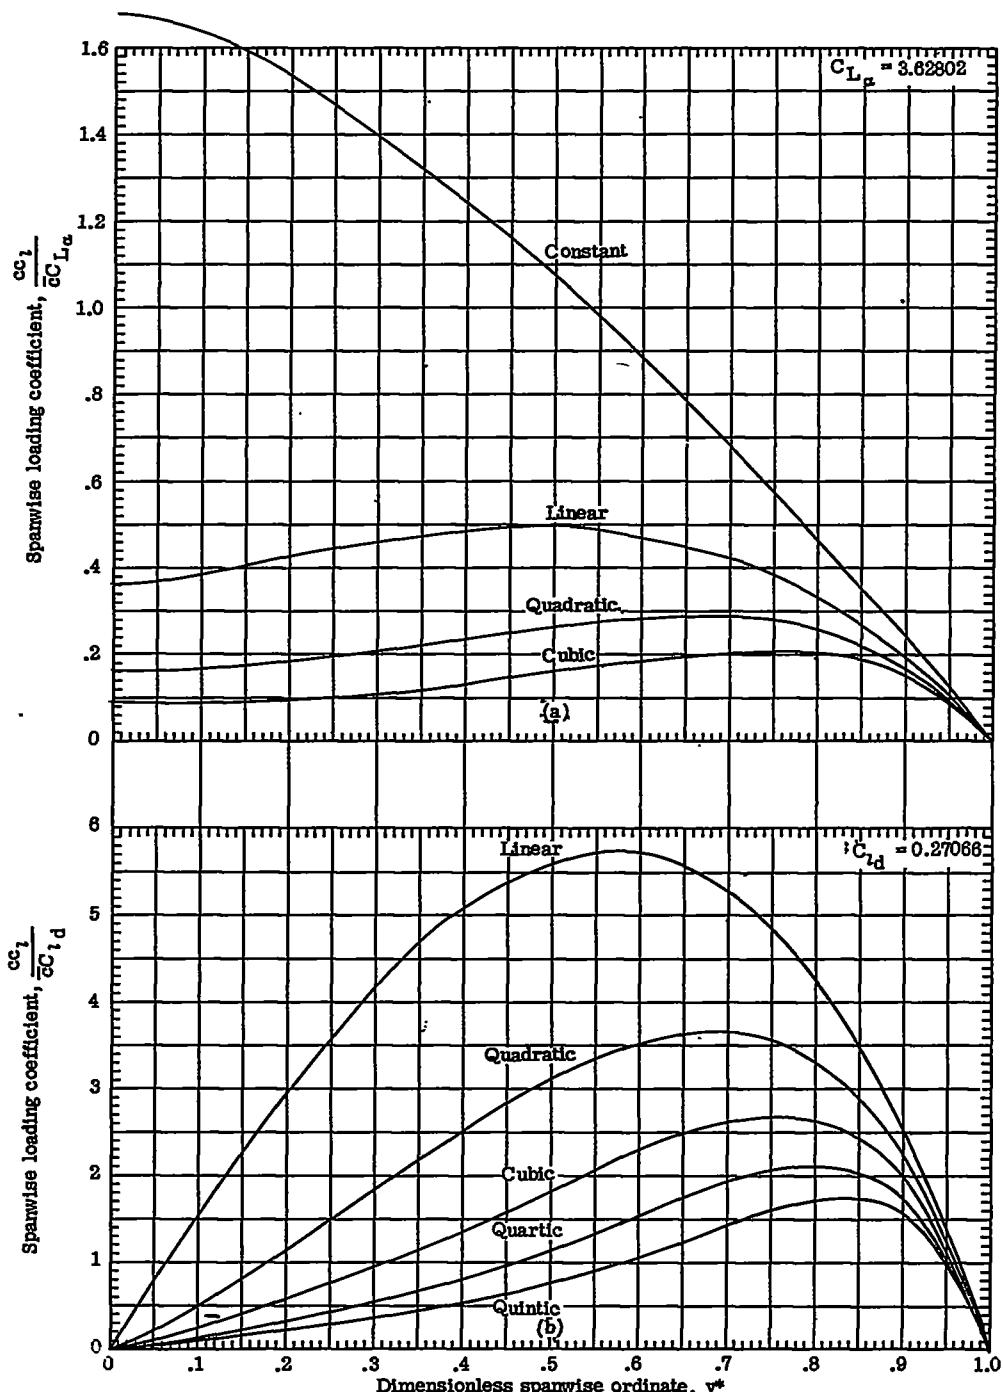

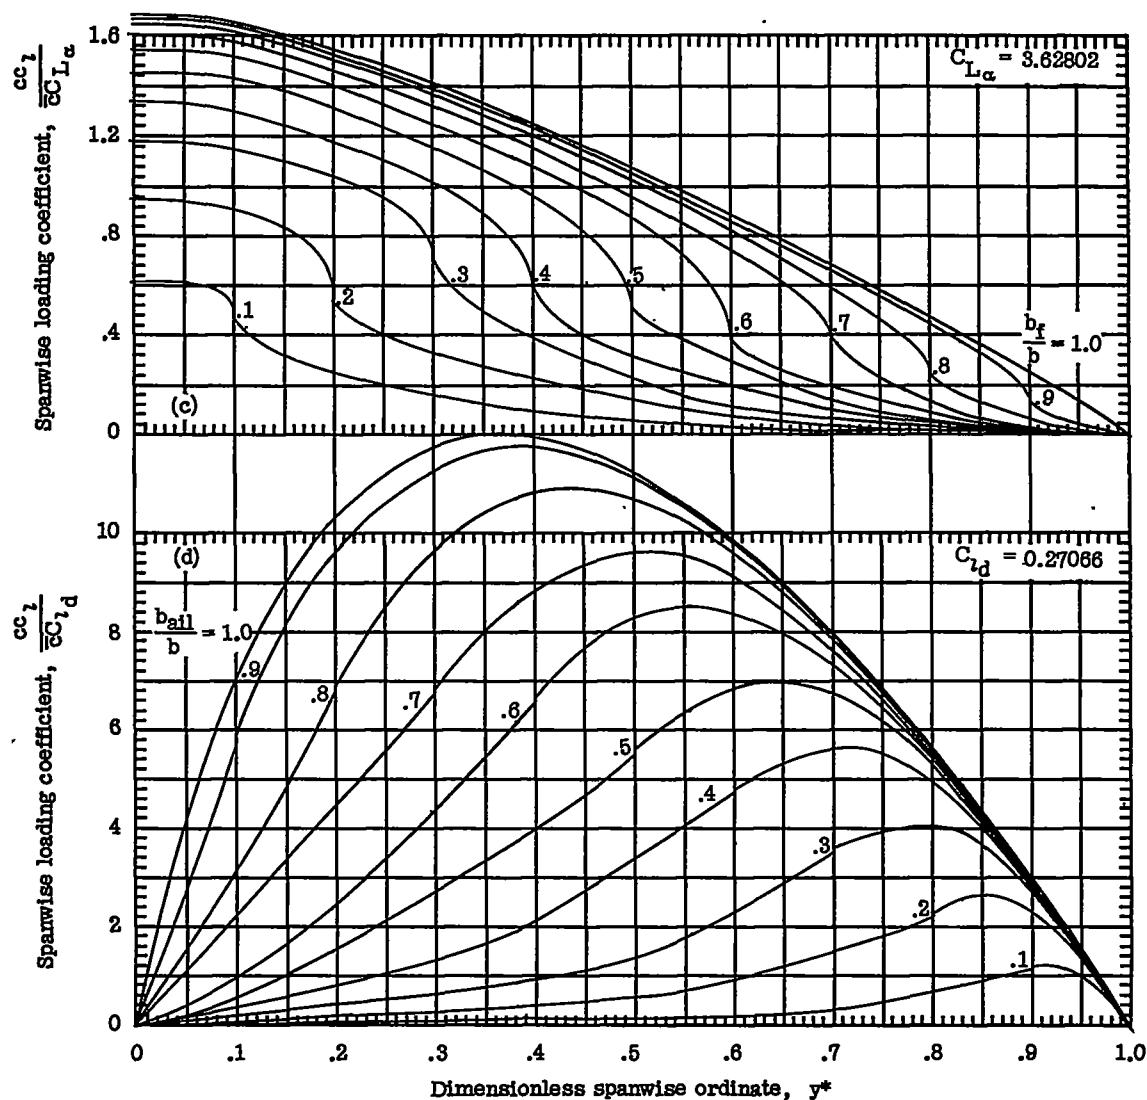

Figure 16.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

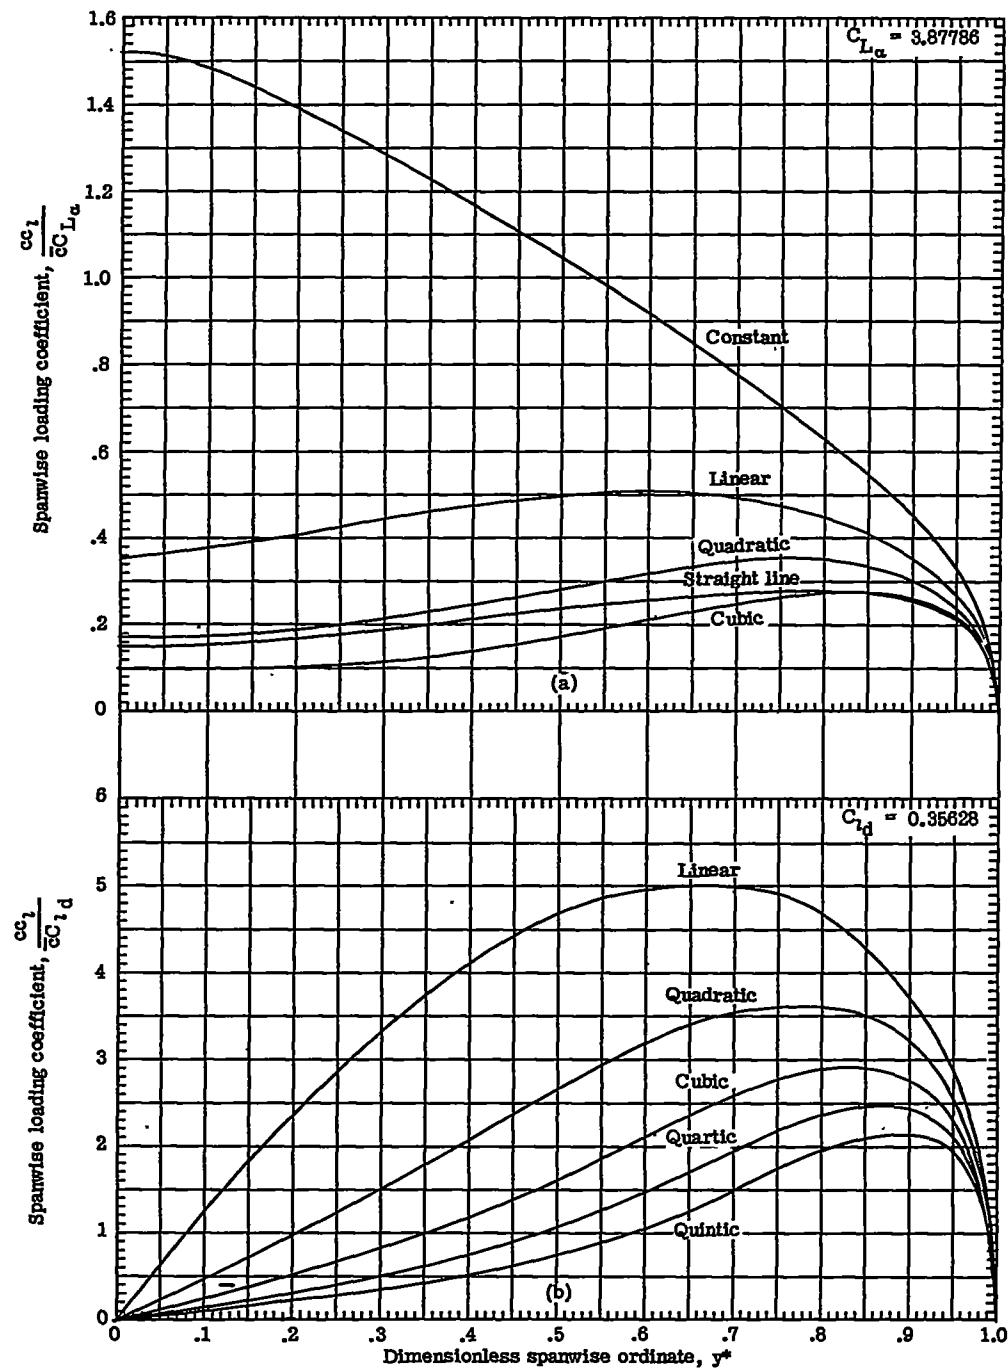

Figure 17.- Spanwise lift distributions for plan form 231 ($A = 6.0$;
 $\lambda = 0$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

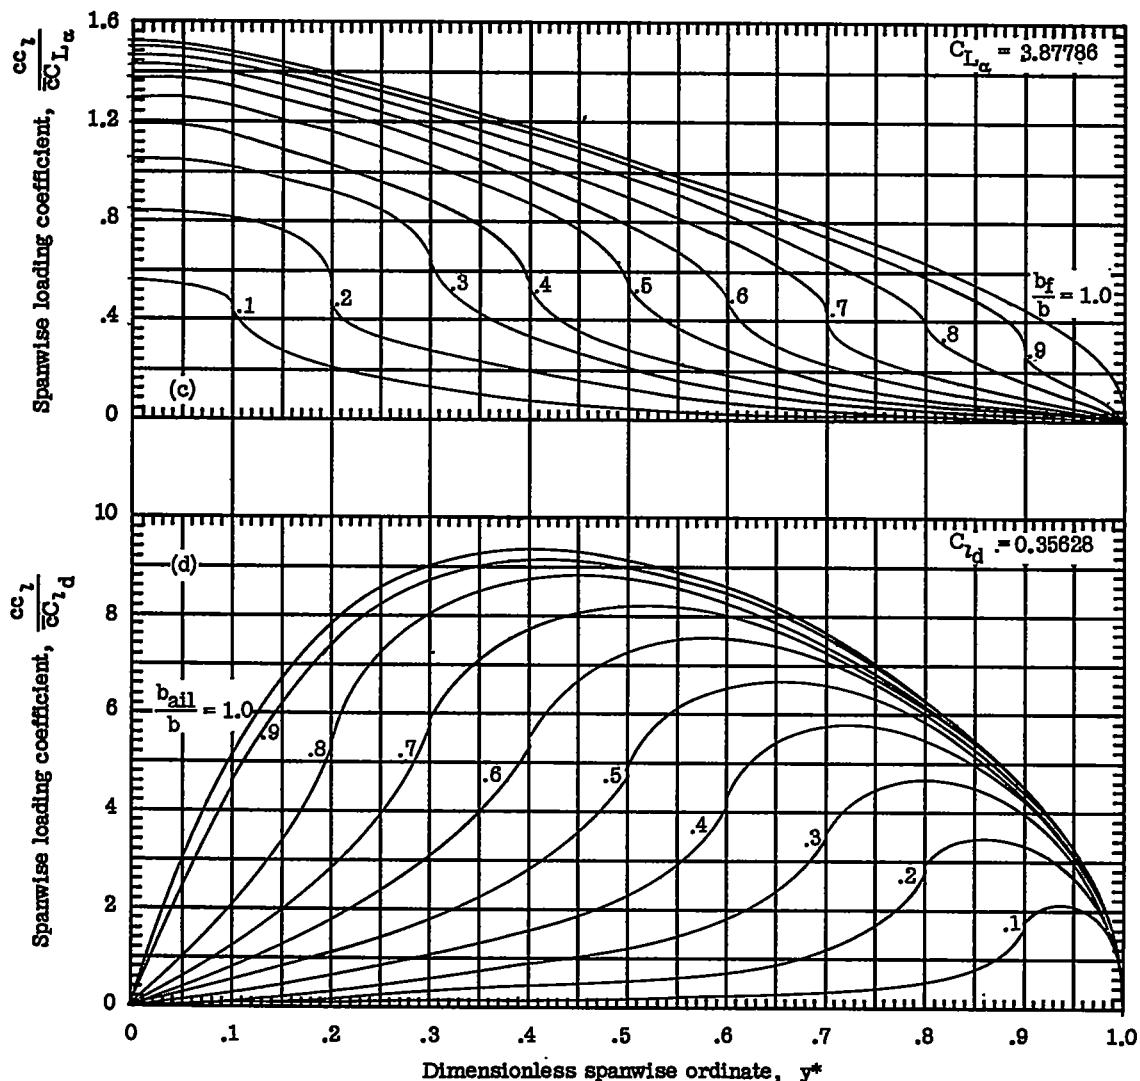

Figure 17.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 18.- Spanwise lift distributions for plan form 232 ($A = 6.0$; $\lambda = 0.25$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 18.- Concluded.

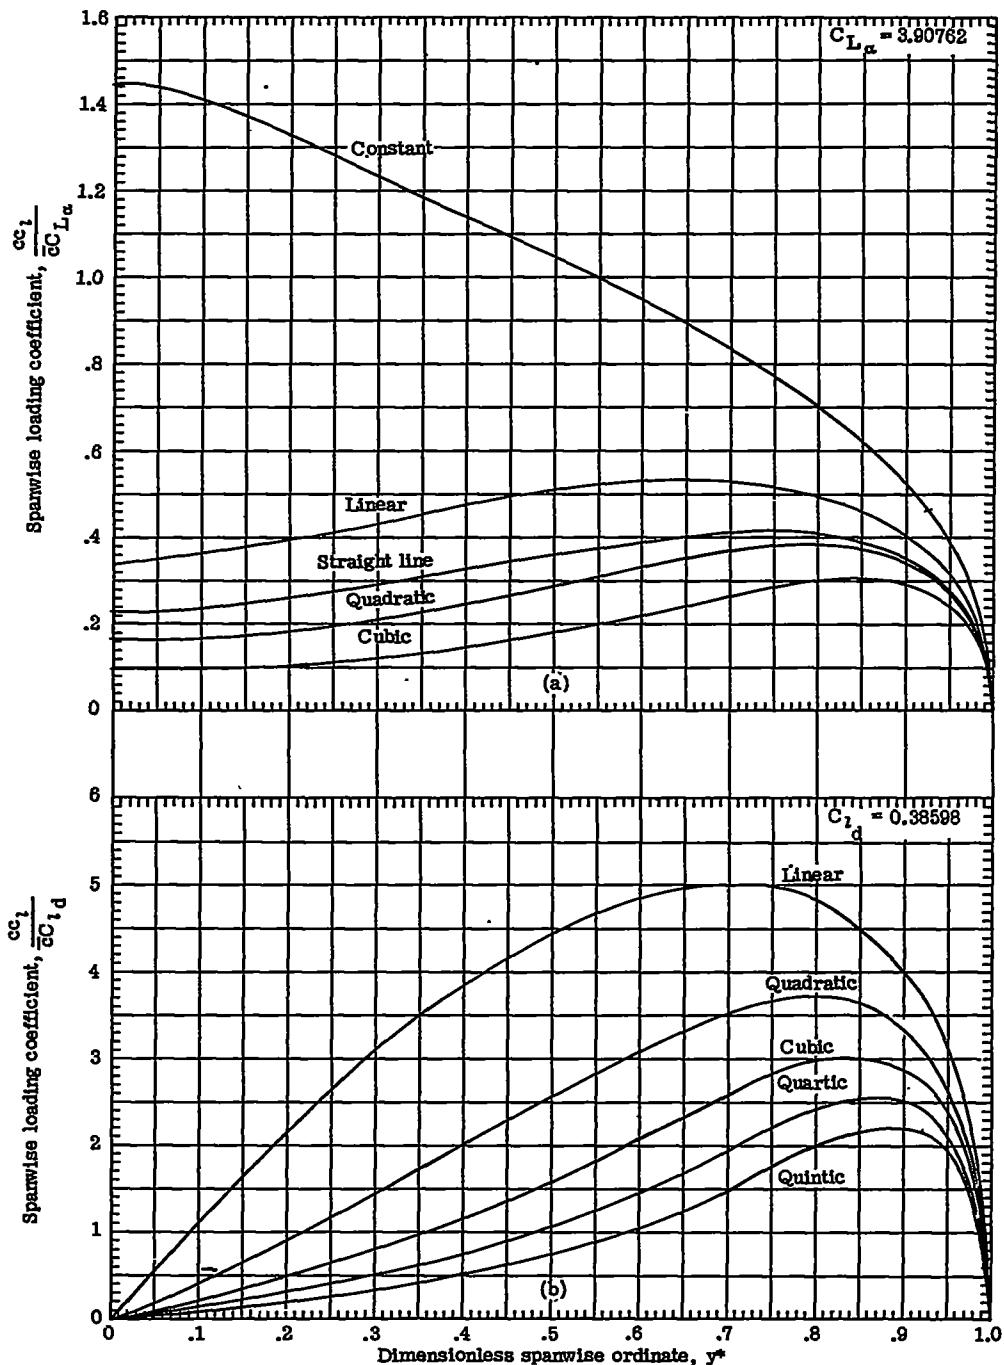

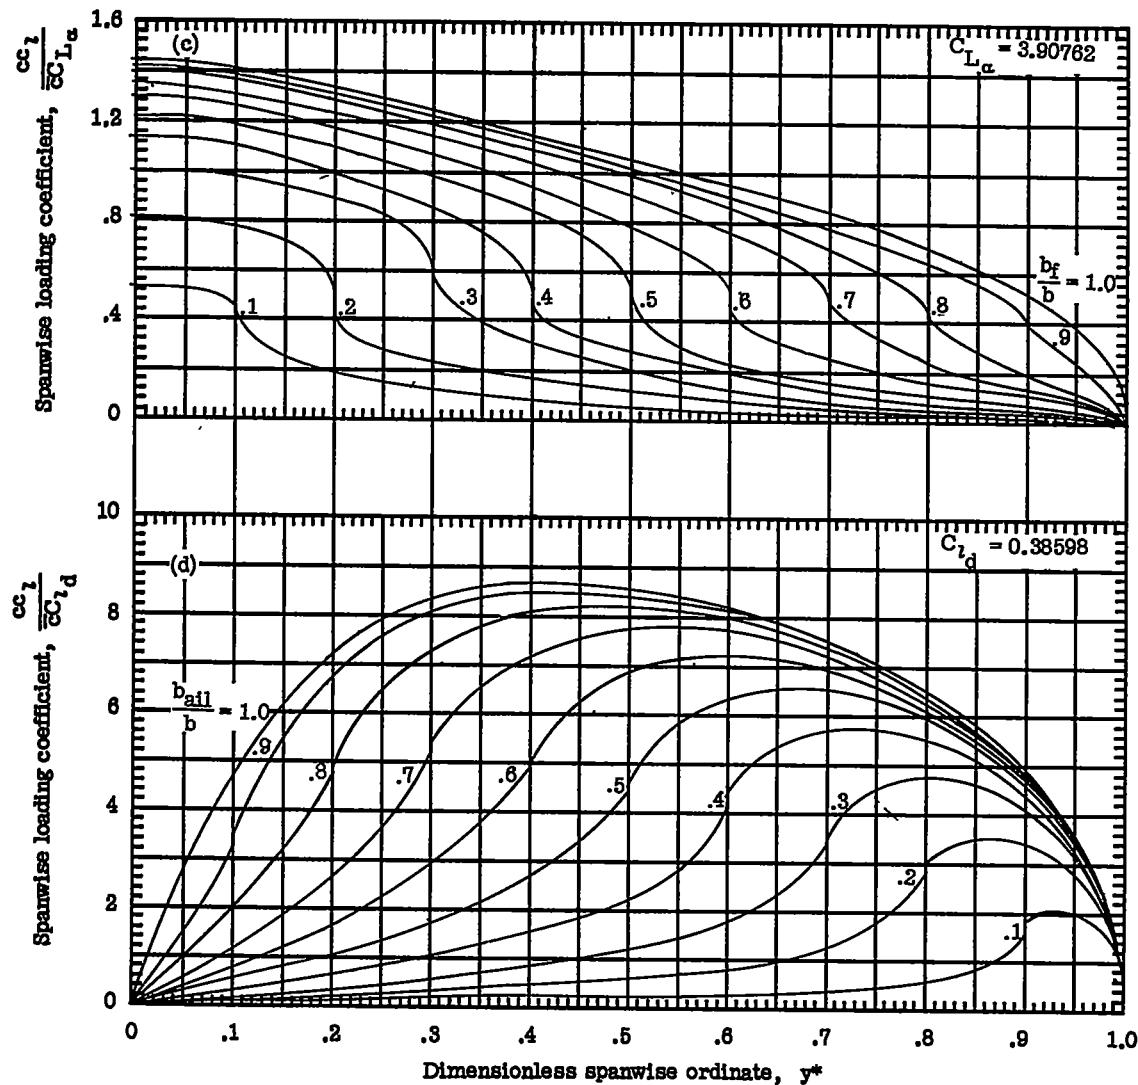

Figure 19.- Spanwise lift distributions for plan form 233 ($A = 6.0$; $\lambda = 0.50$; $\Lambda = -30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 19.- Concluded.

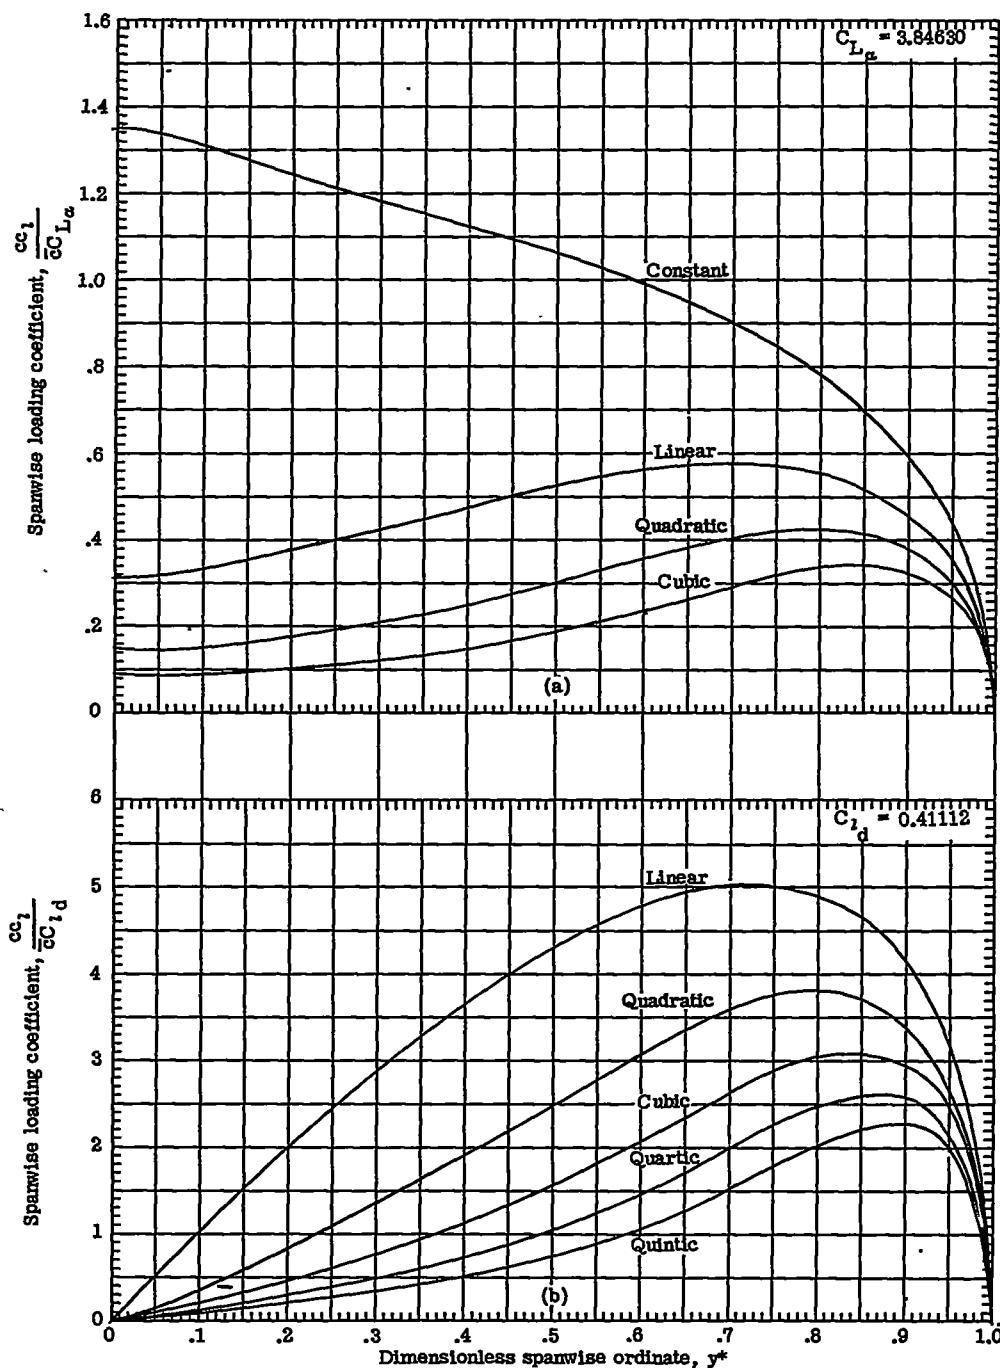

Figure 20.- Spanwise lift distributions for plan form 234 ($A = 6.0$; $\lambda = 1.00$; $\Lambda = -30^\circ$).

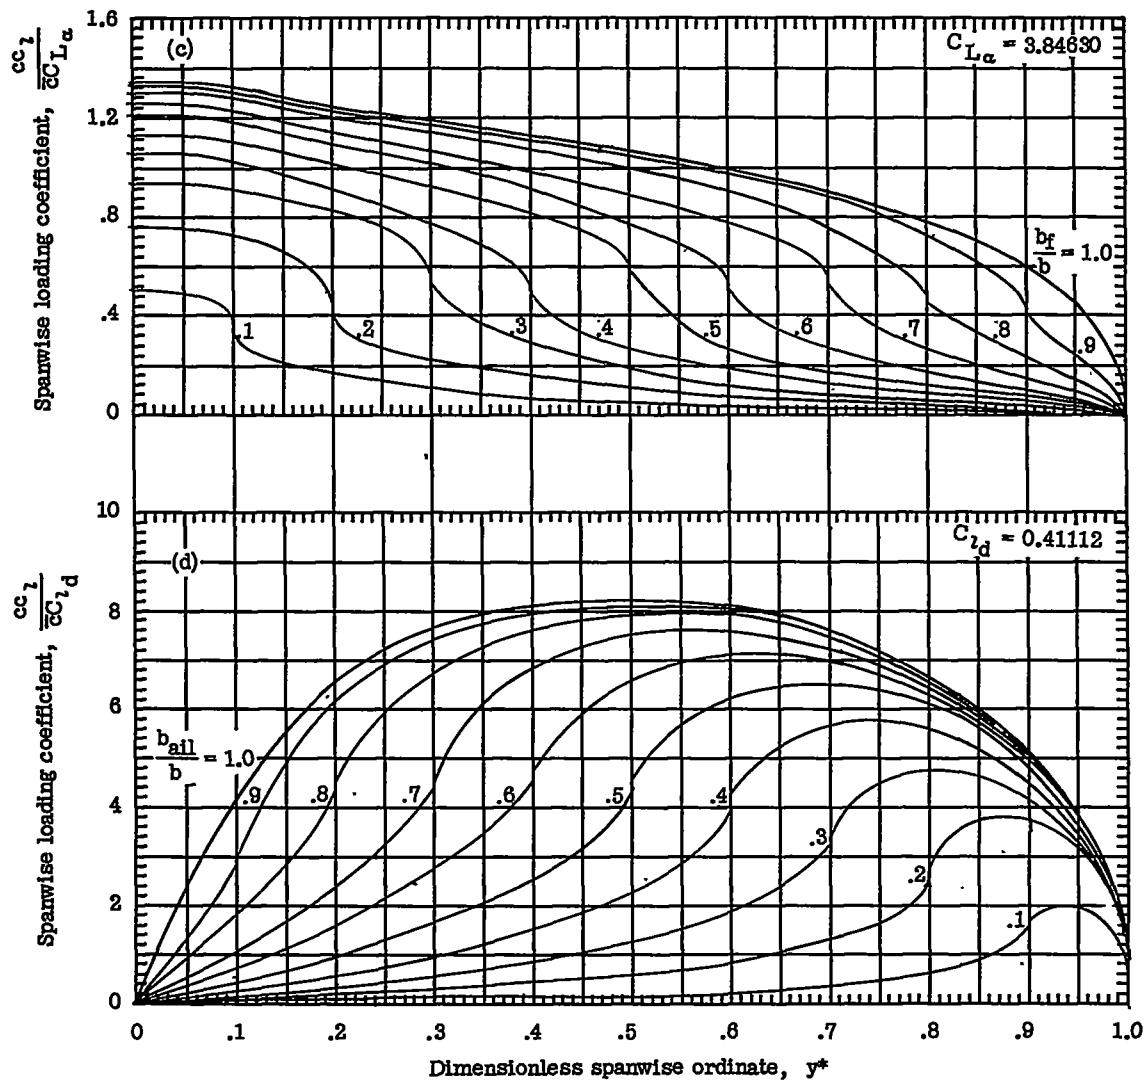

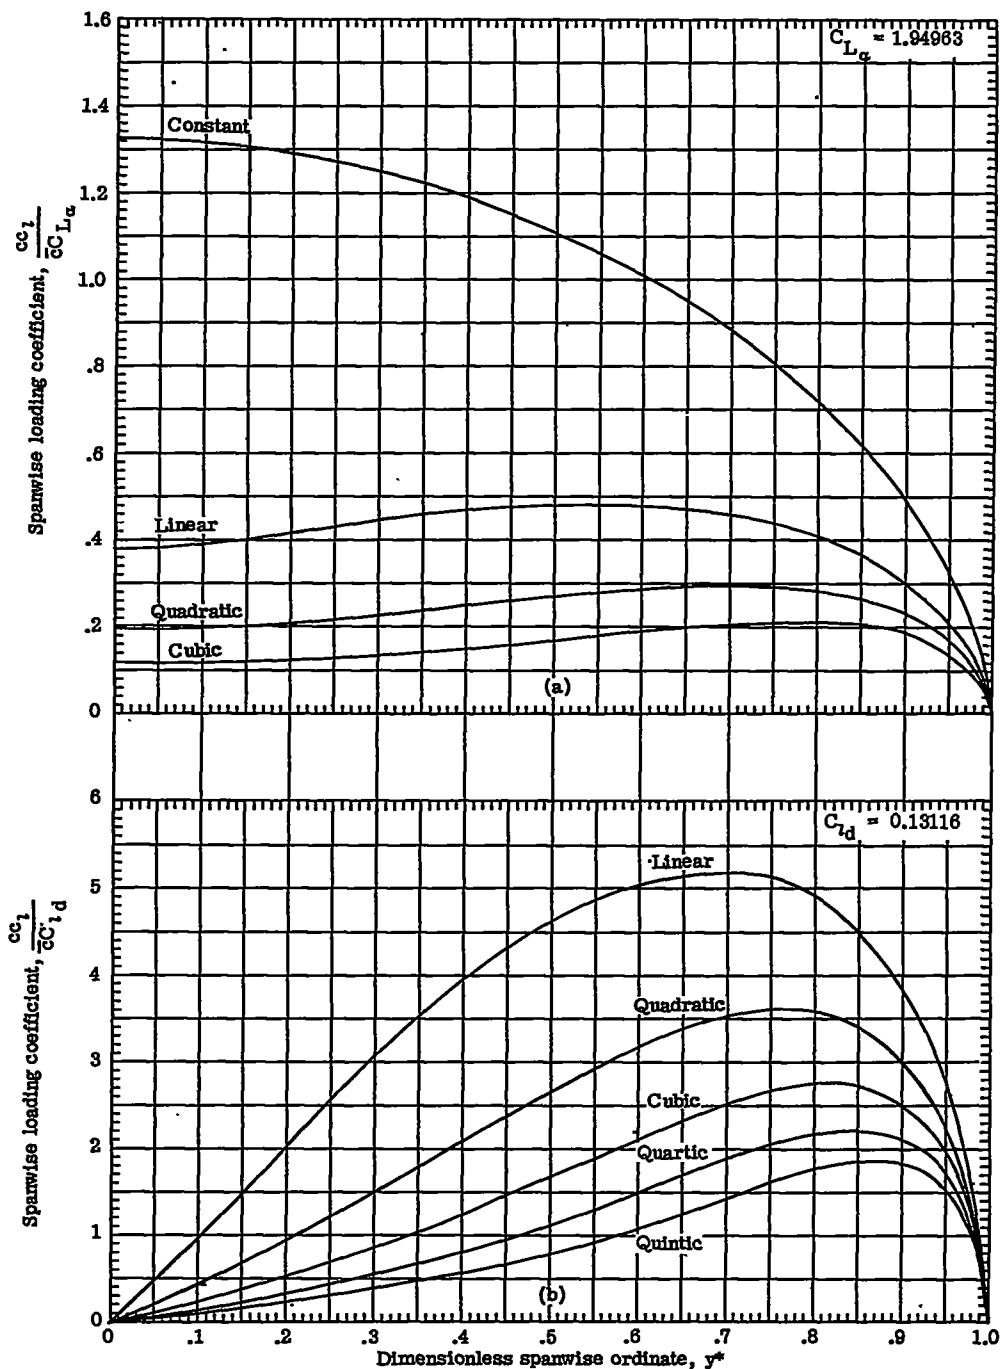

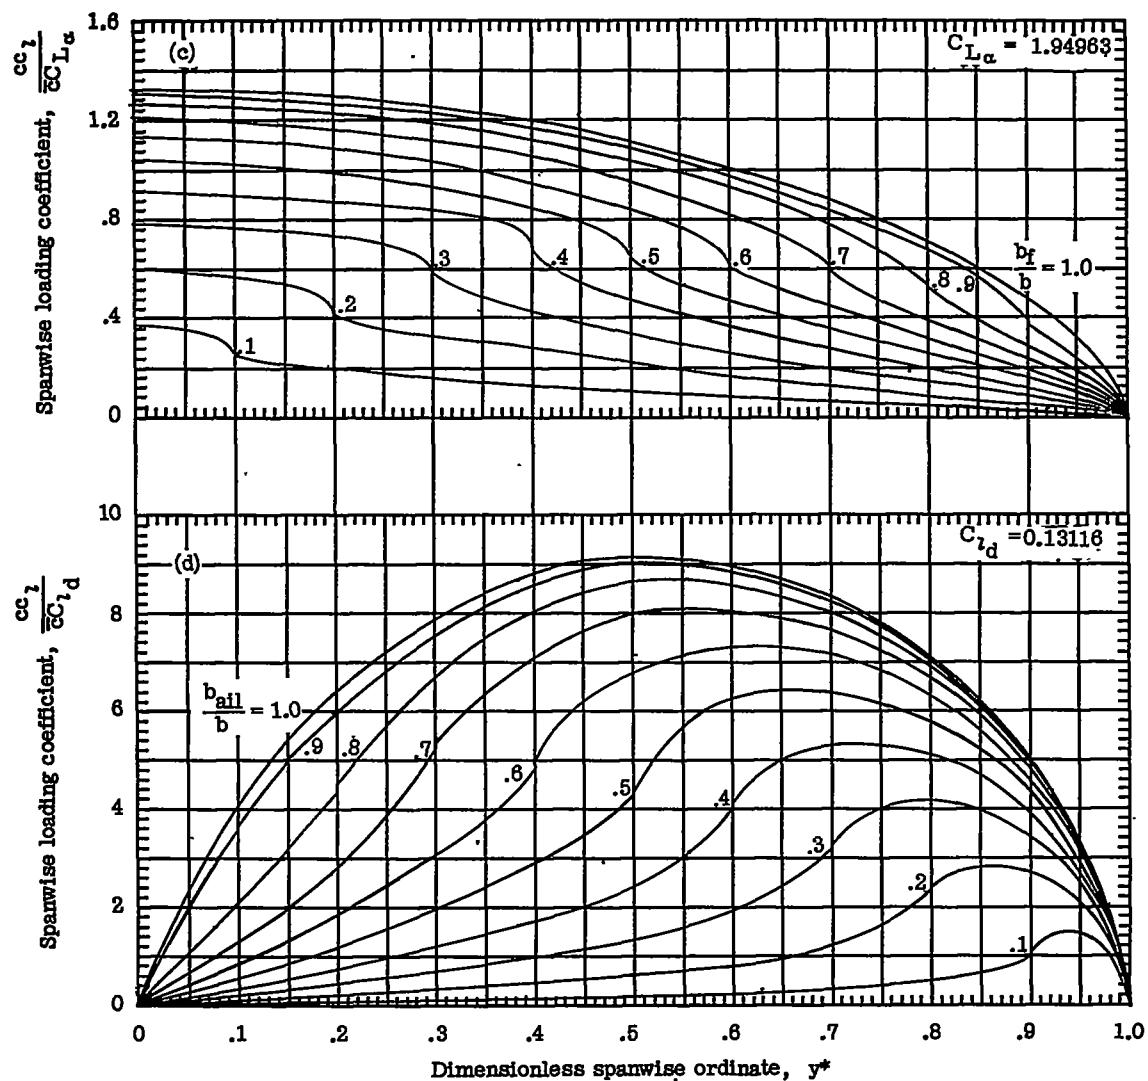

Figure 20.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 21.- Spanwise lift distributions for plan form 411 ($A = 1.5$;
 $\lambda = 0$; $\Lambda = 30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 21.- Concluded.

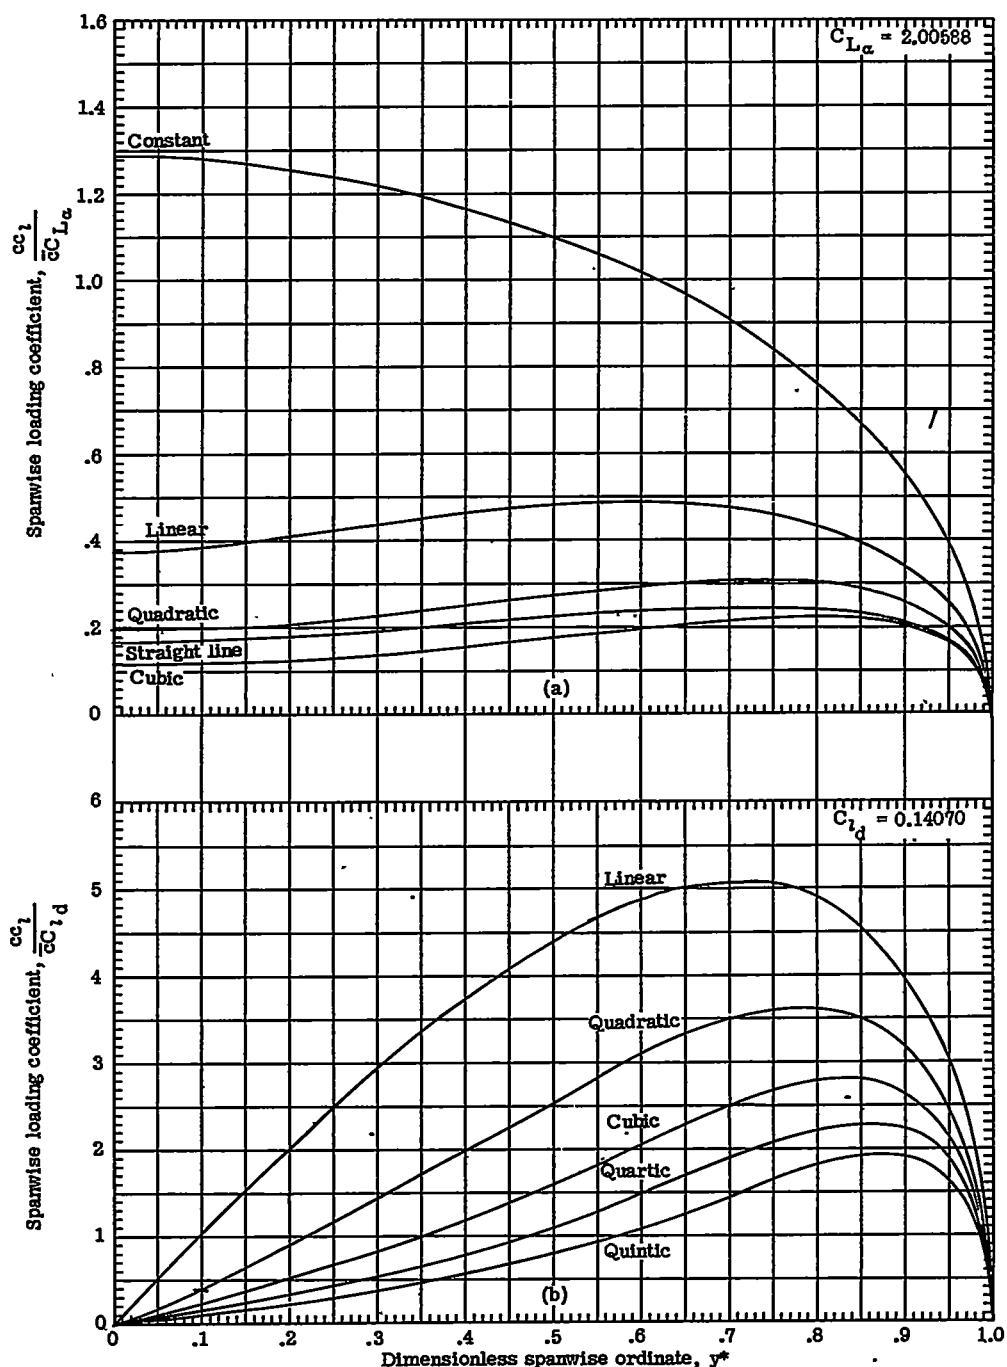

Figure 22.- Spanwise lift distributions for plan form 412 ($A = 1.5$;
 $\lambda = 0.25$; $\Lambda = 30^\circ$).

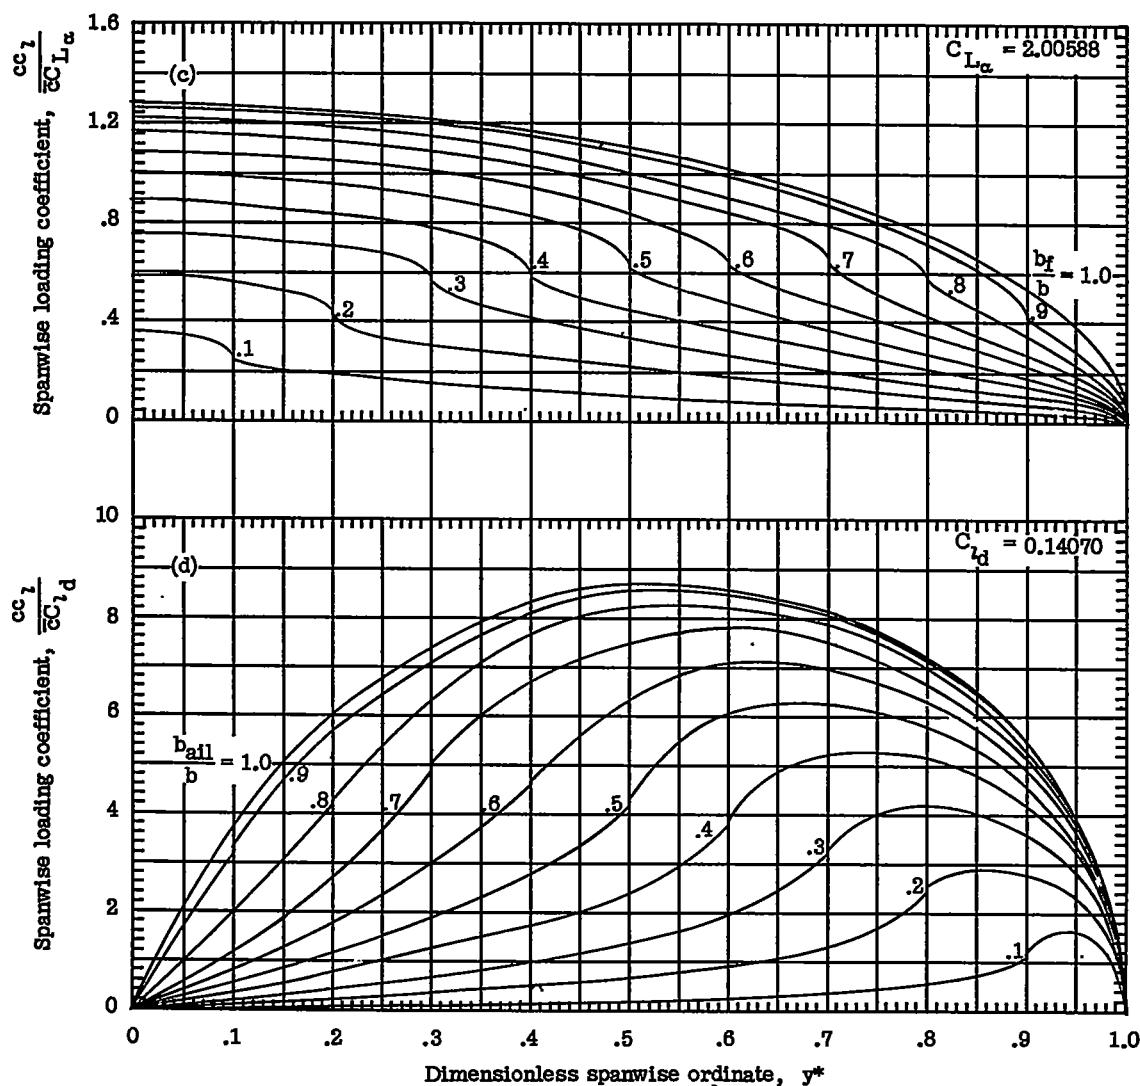

Figure 22.- Concluded.

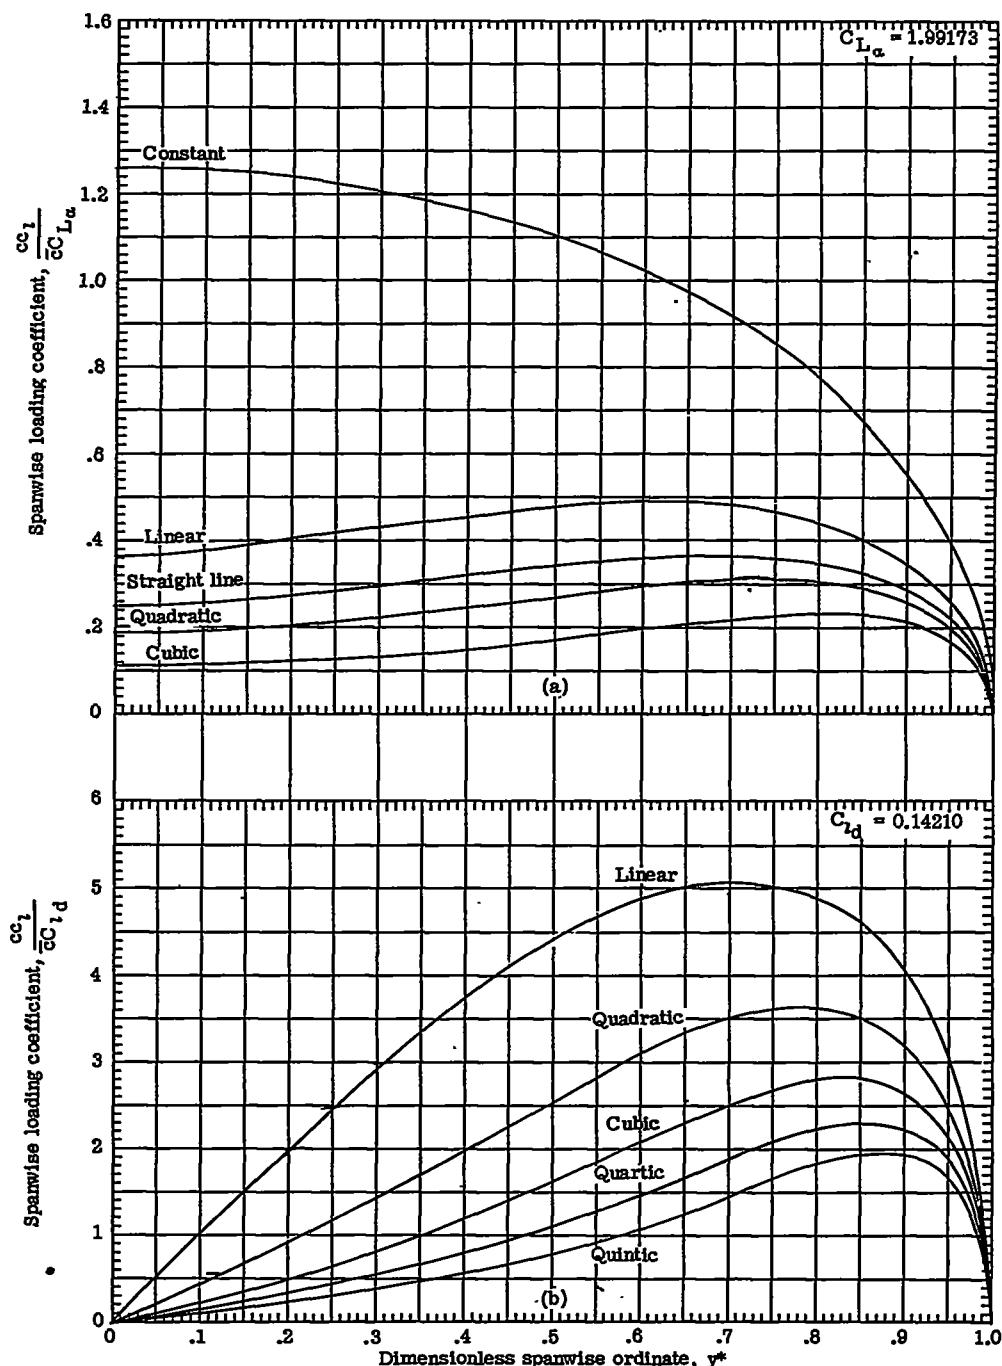

Figure 23.- Spanwise lift distributions for plan form 413 ($A = 1.5$; $\lambda = 0.50$; $\Lambda = 30^\circ$).

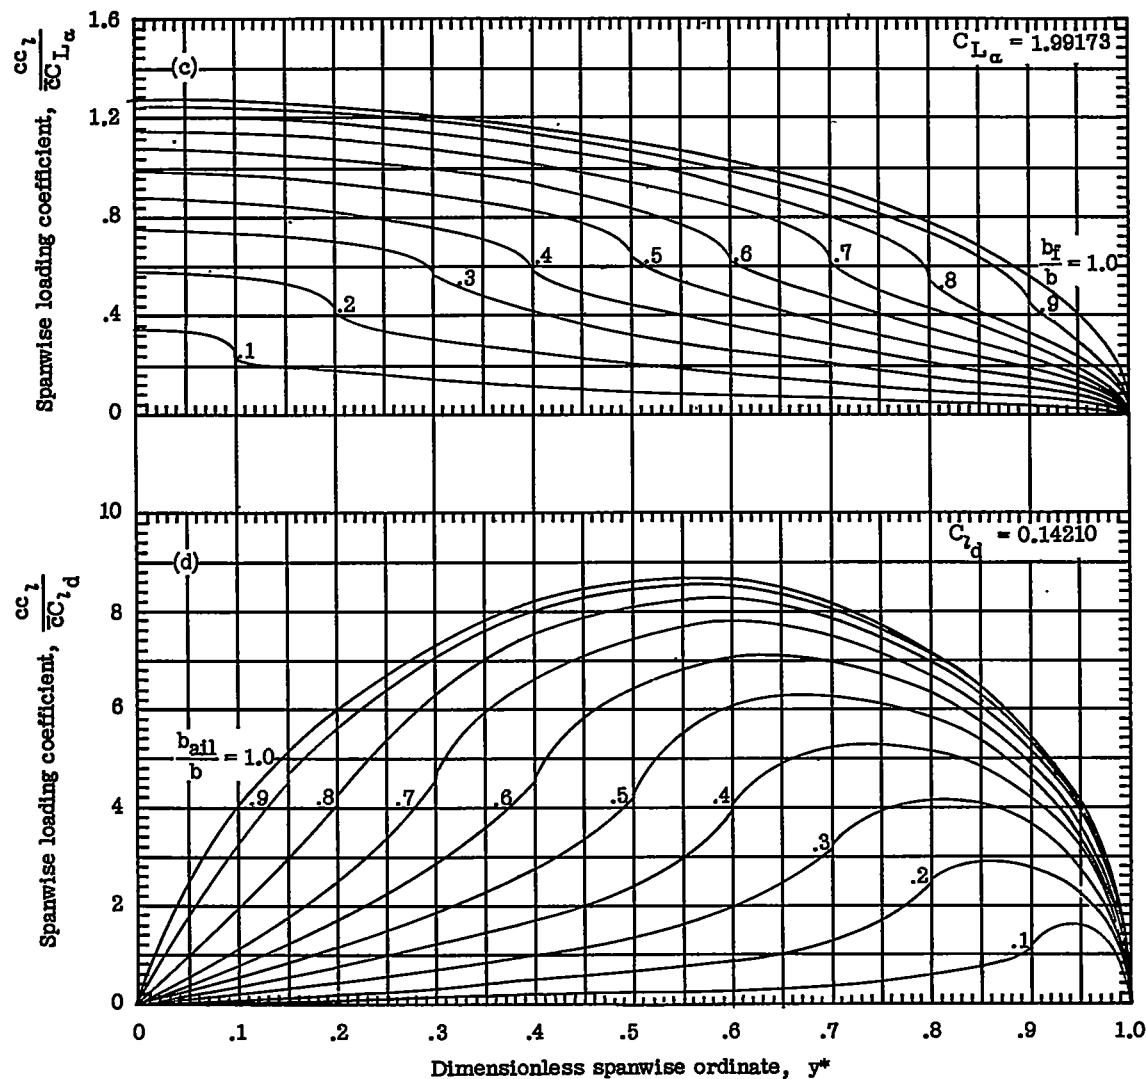

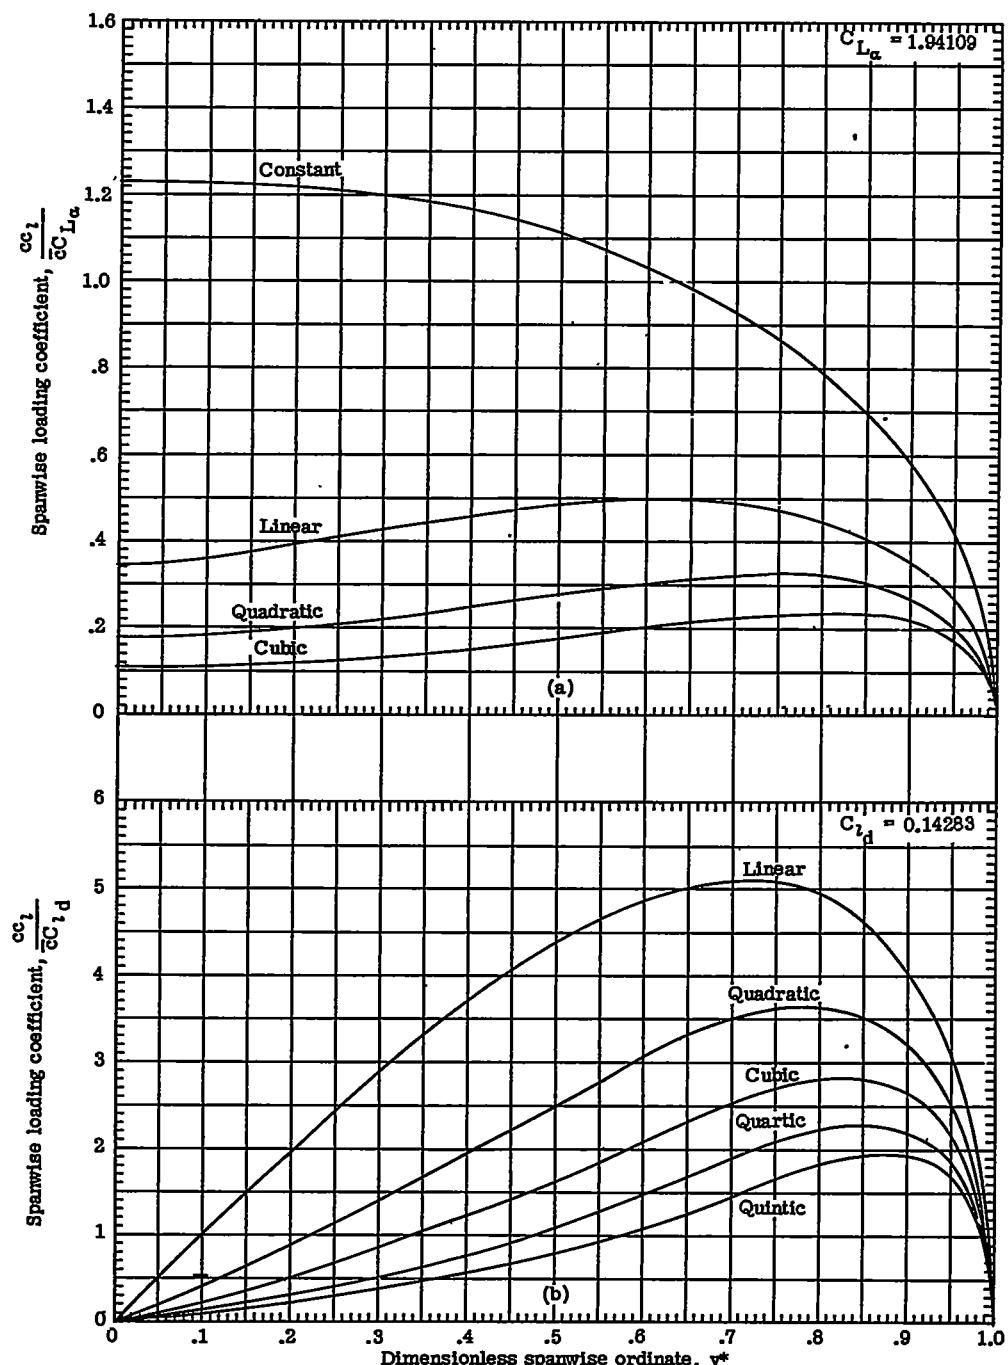

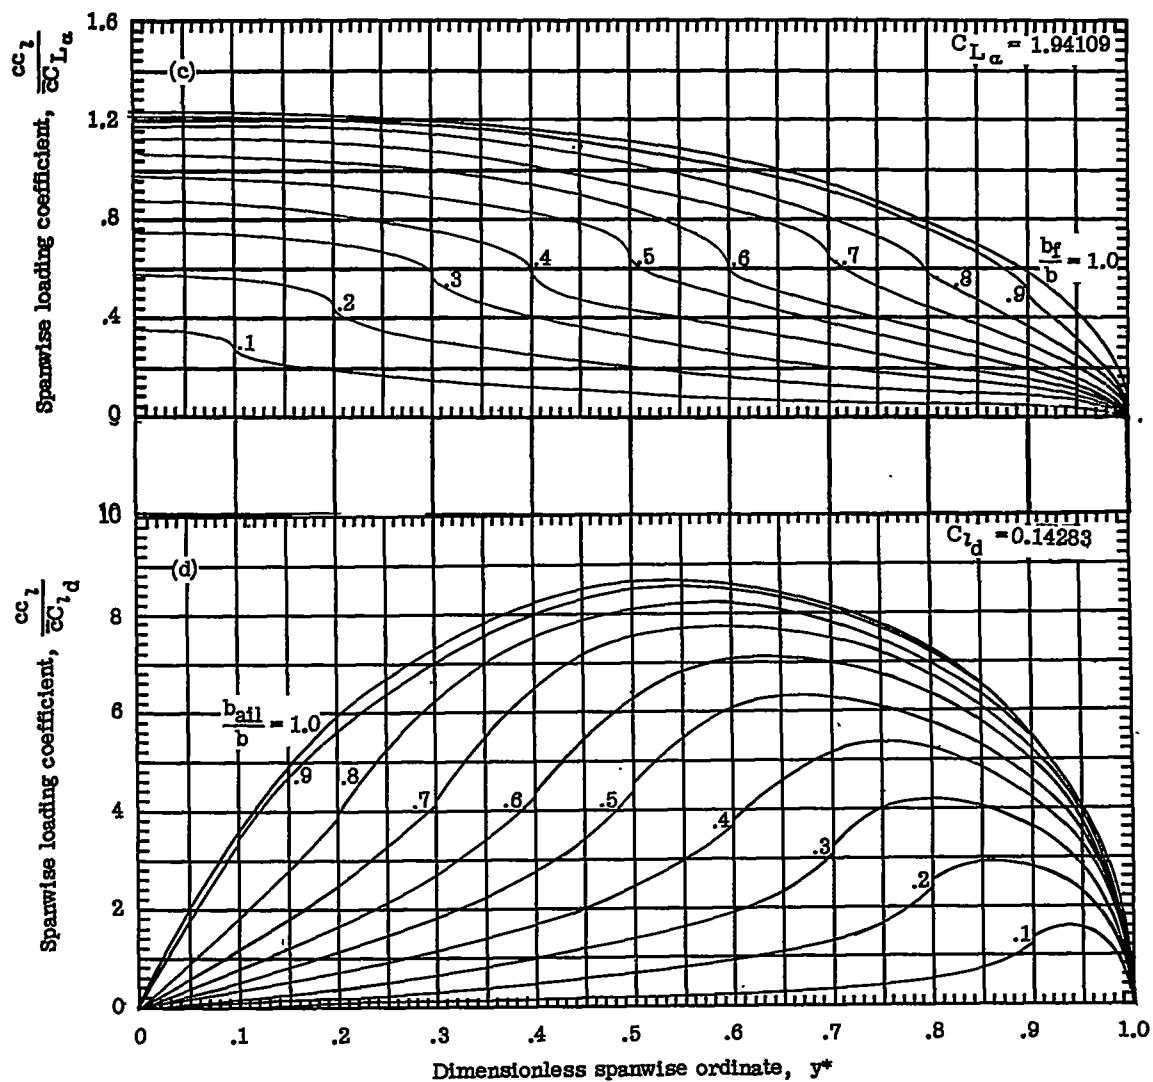

Figure 23.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

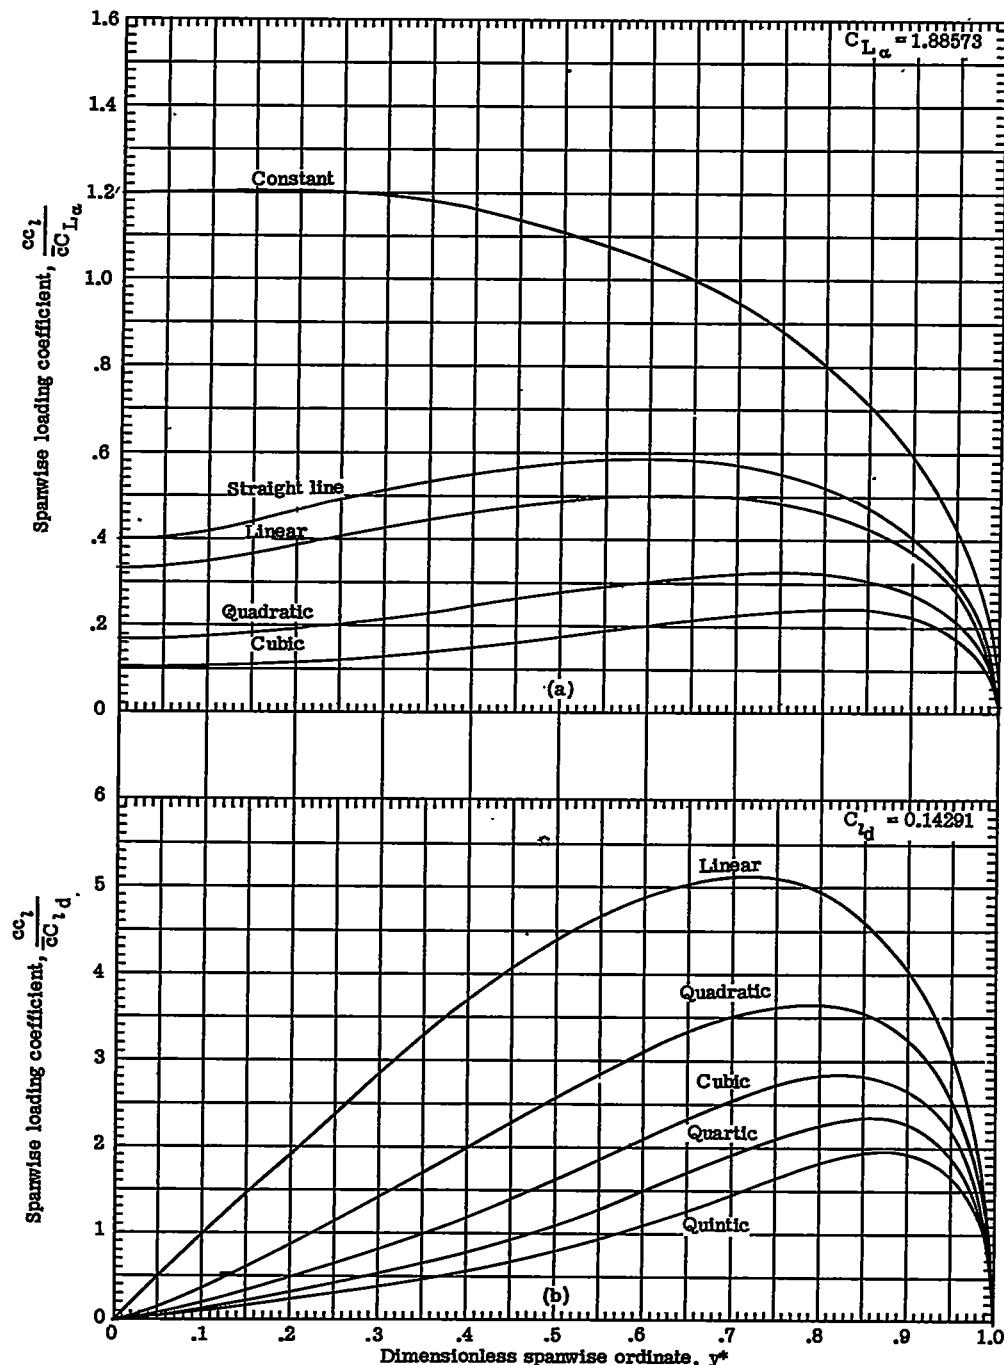

Figure 24.- Spanwise lift distributions for plan form 414 ($A = 1.5$; $\lambda = 1.00$; $\Lambda = 30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.

Figure 24.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 25.- Spanwise lift distributions for plan form 415 ($A = 1.5$; $\lambda = 1.50$; $\Lambda = 30^\circ$).

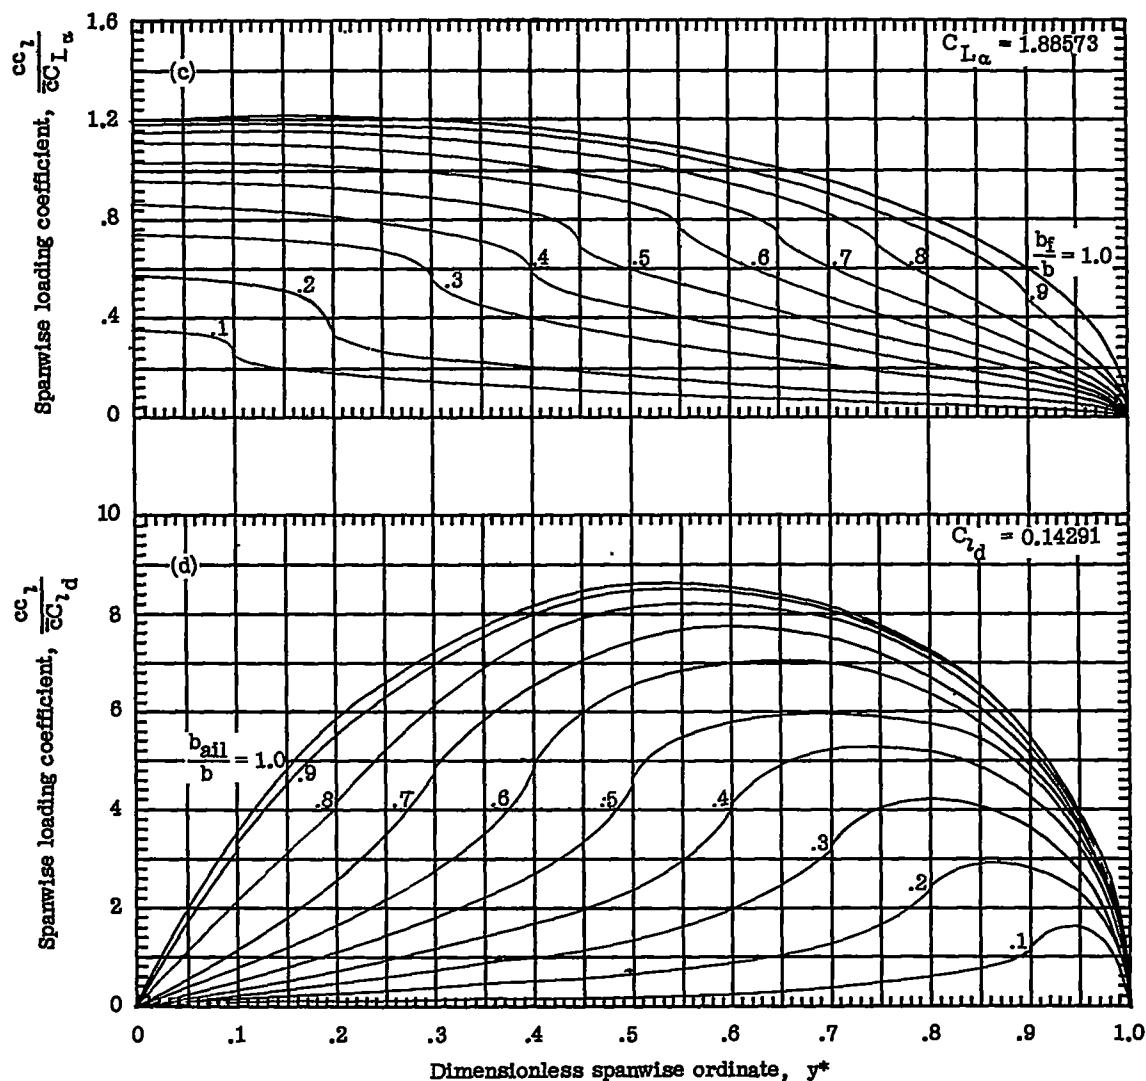

Figure 25.- Concluded.

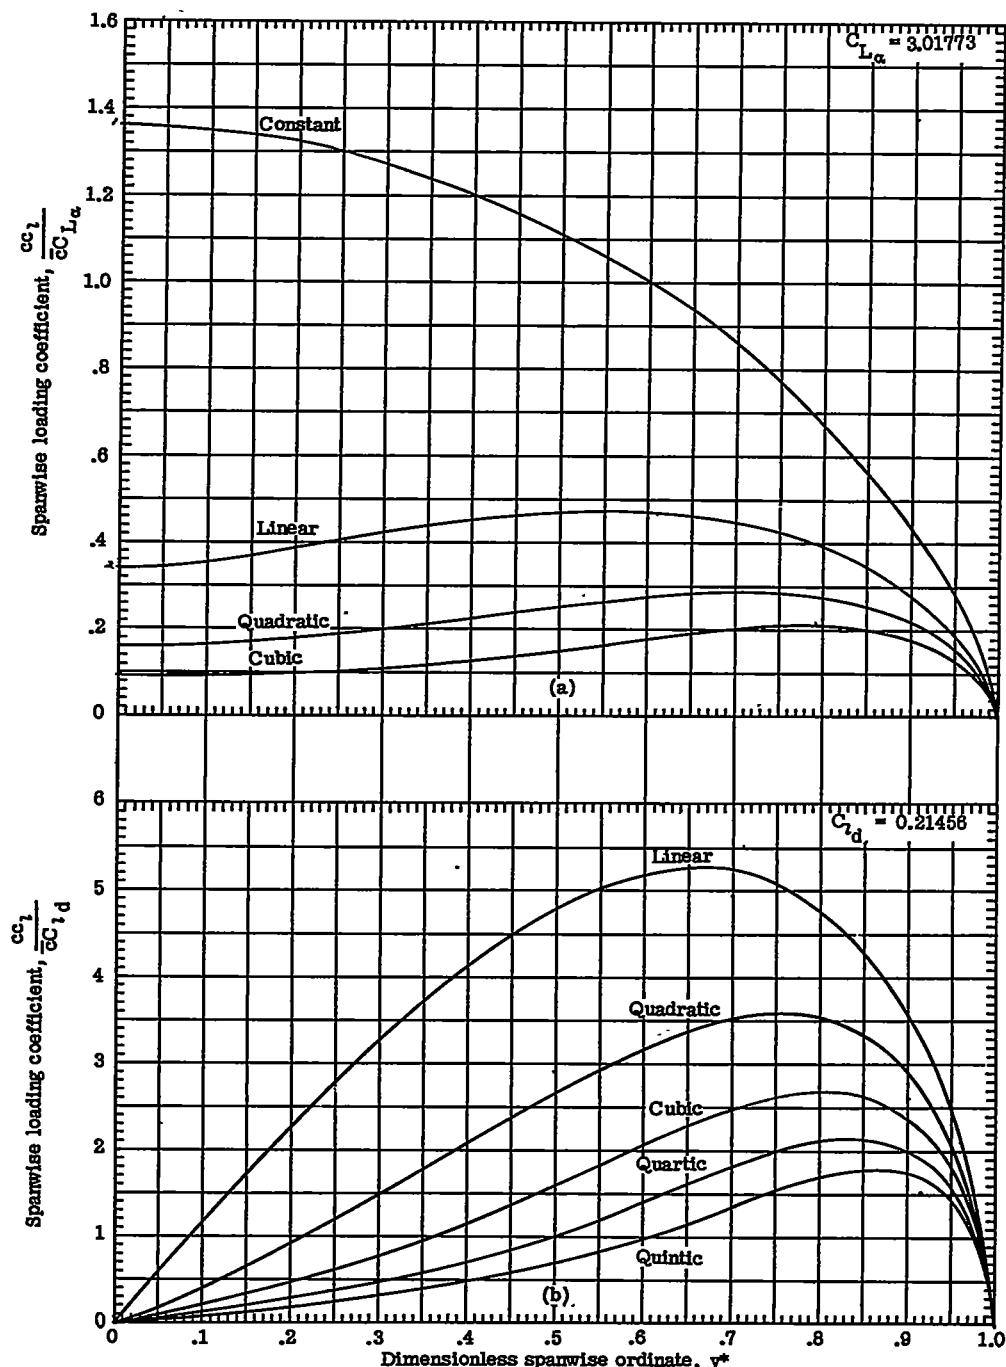

Figure 26.- Spanwise lift distributions for plan form 421 ($A = 3.0$; $\lambda = 0$; $\Lambda = 30^\circ$).

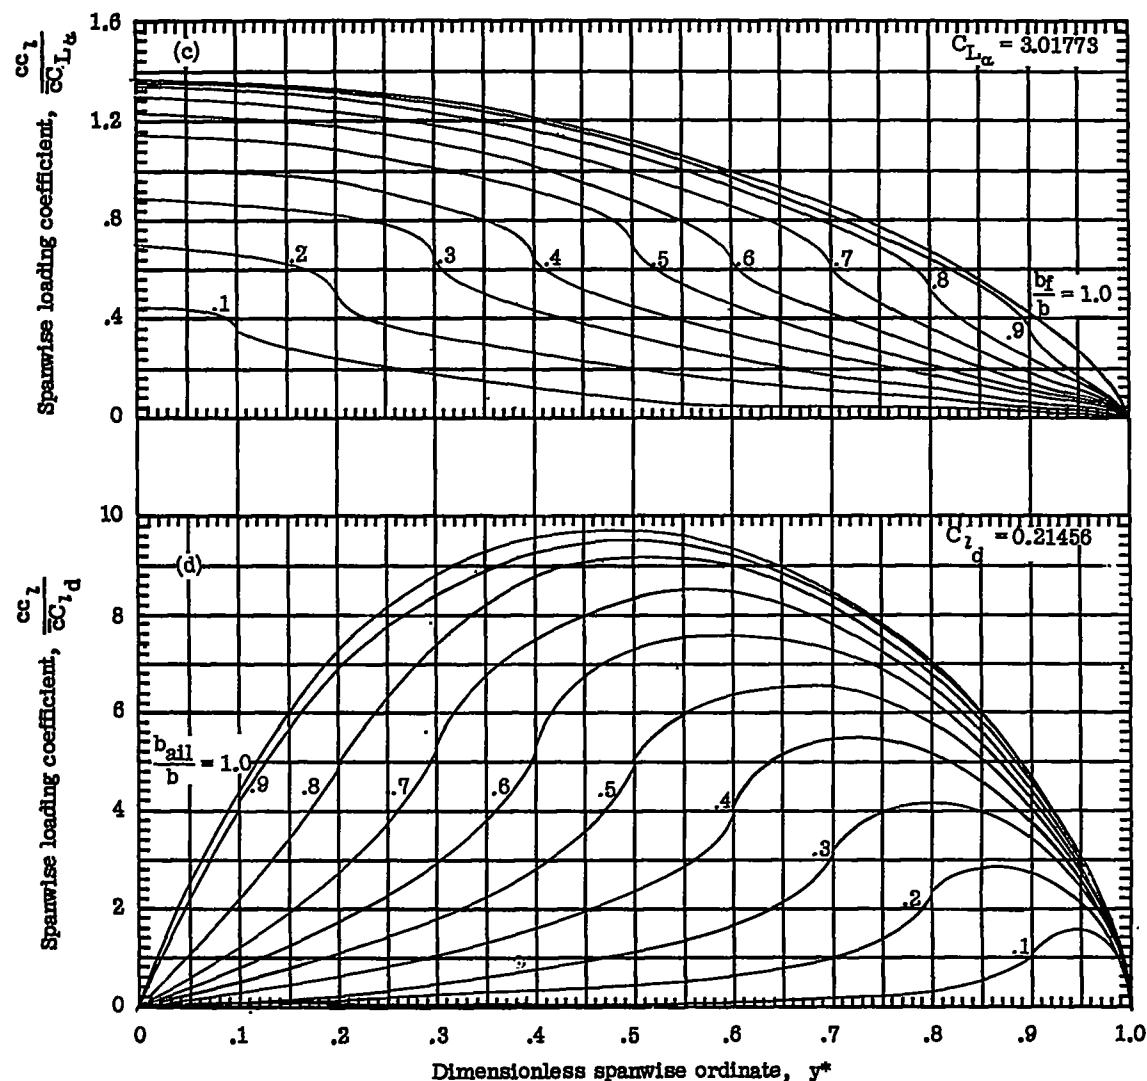

Figure 26.- Concluded.

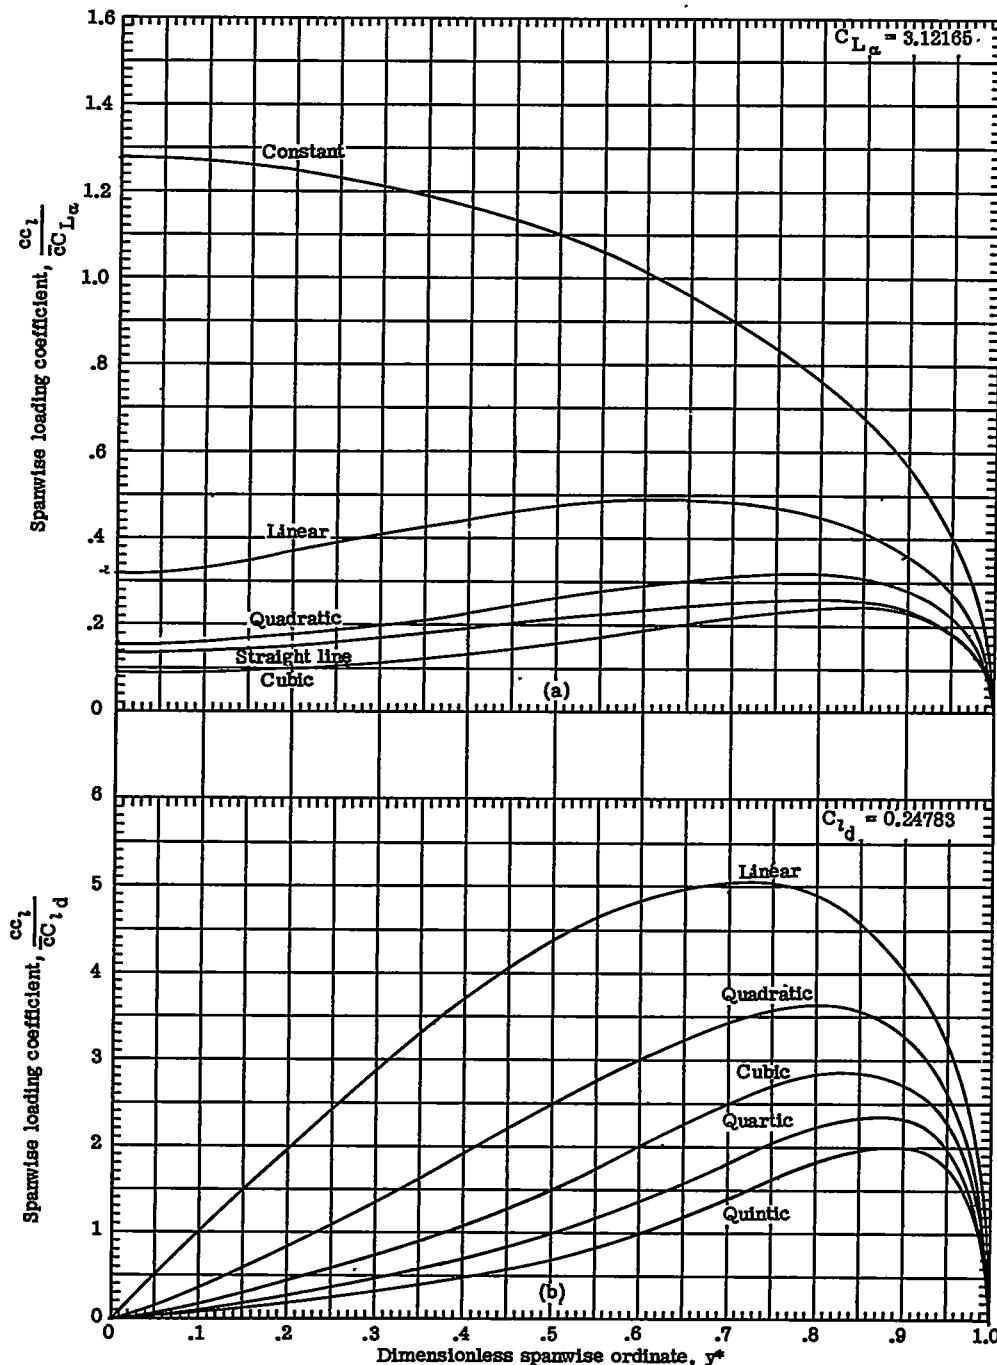

Figure 27.- Spanwise lift distributions for plan form 422 ($A = 3.0$; $\lambda = 0.25$; $\Lambda = 30^\circ$).

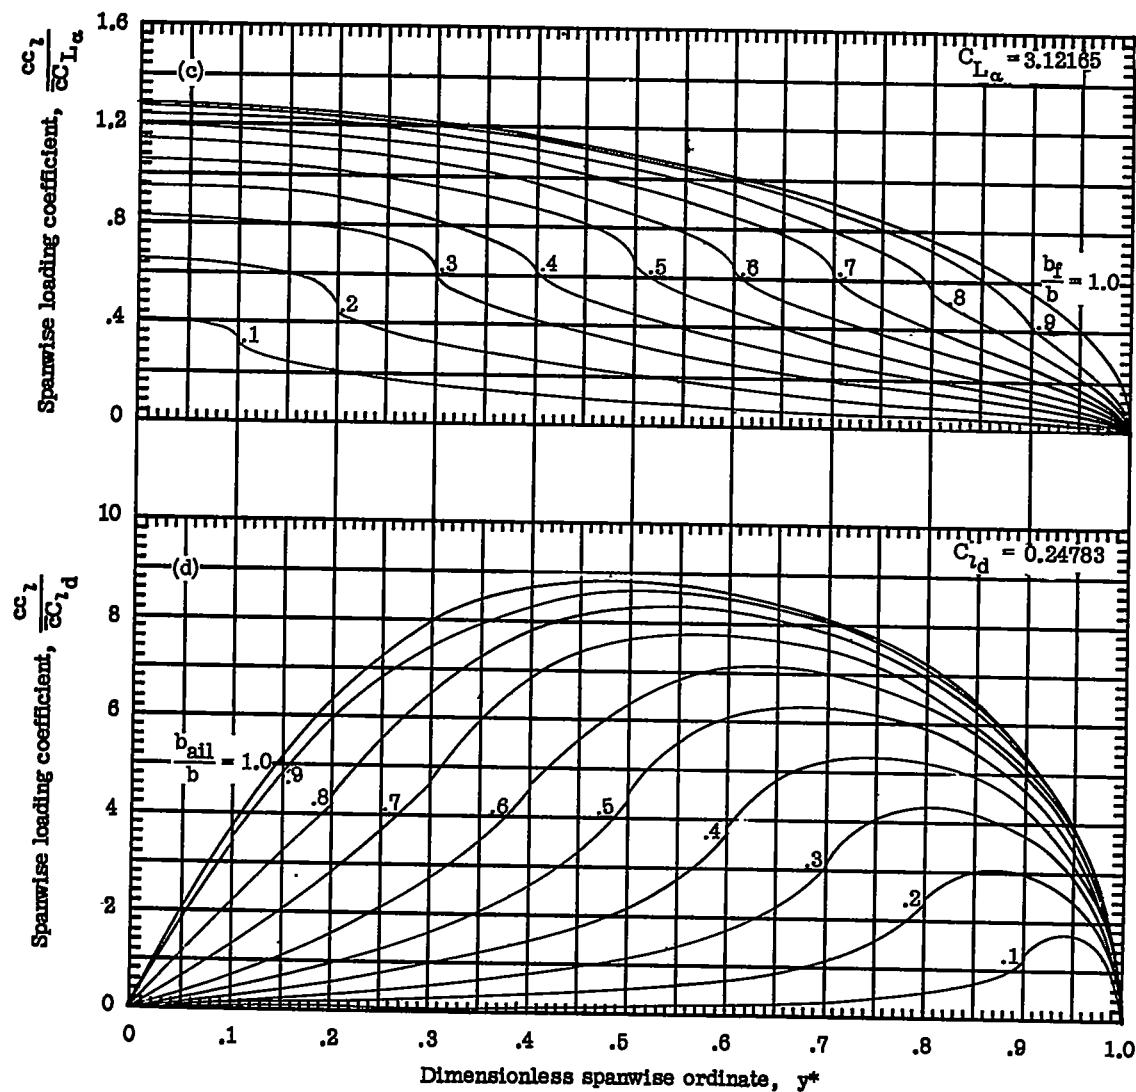

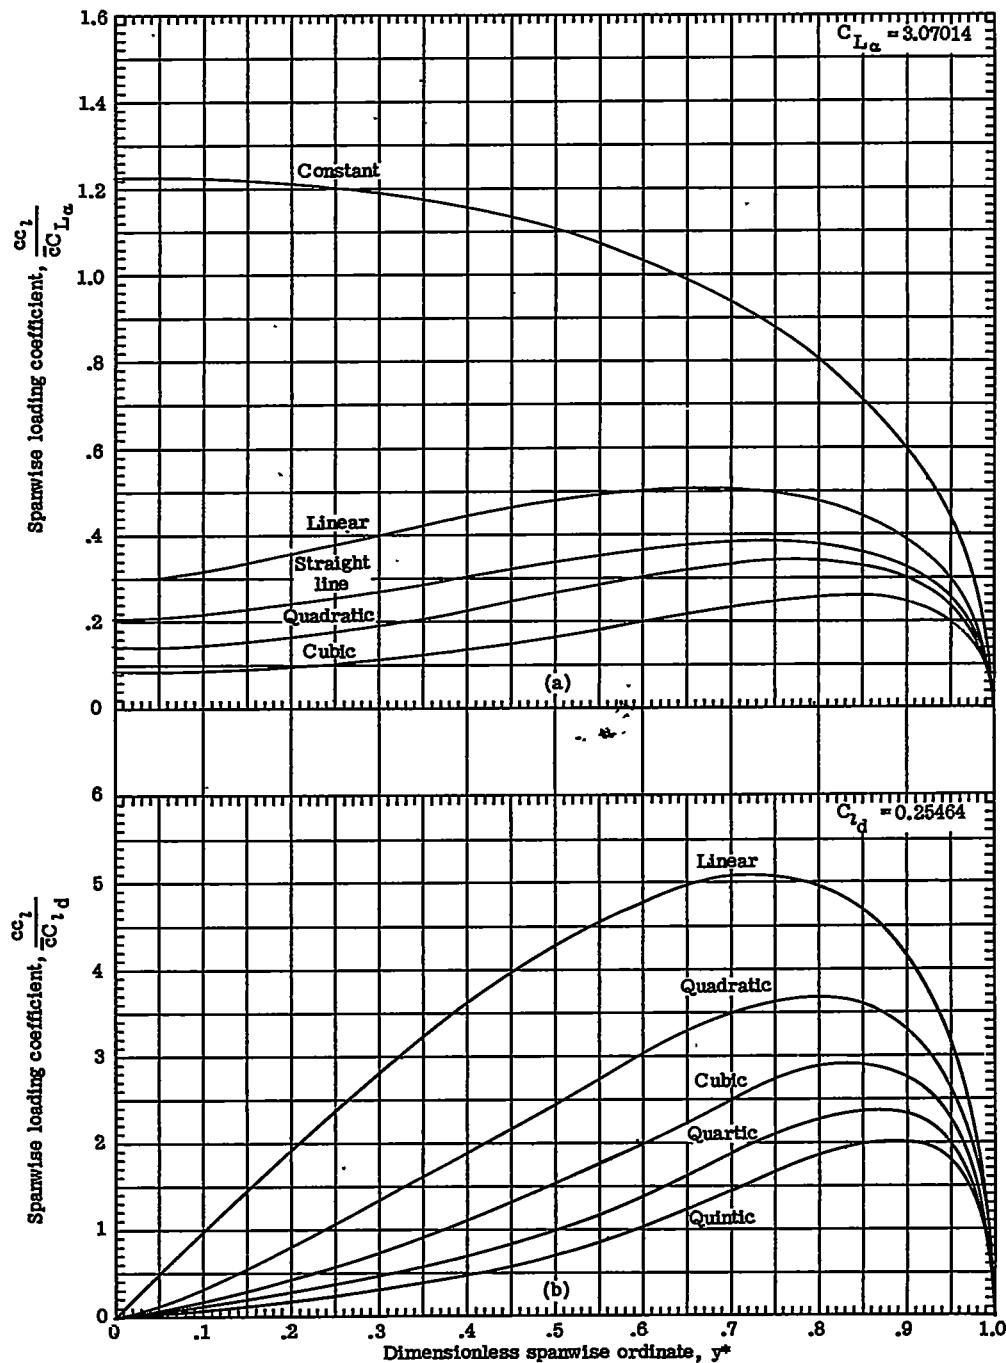

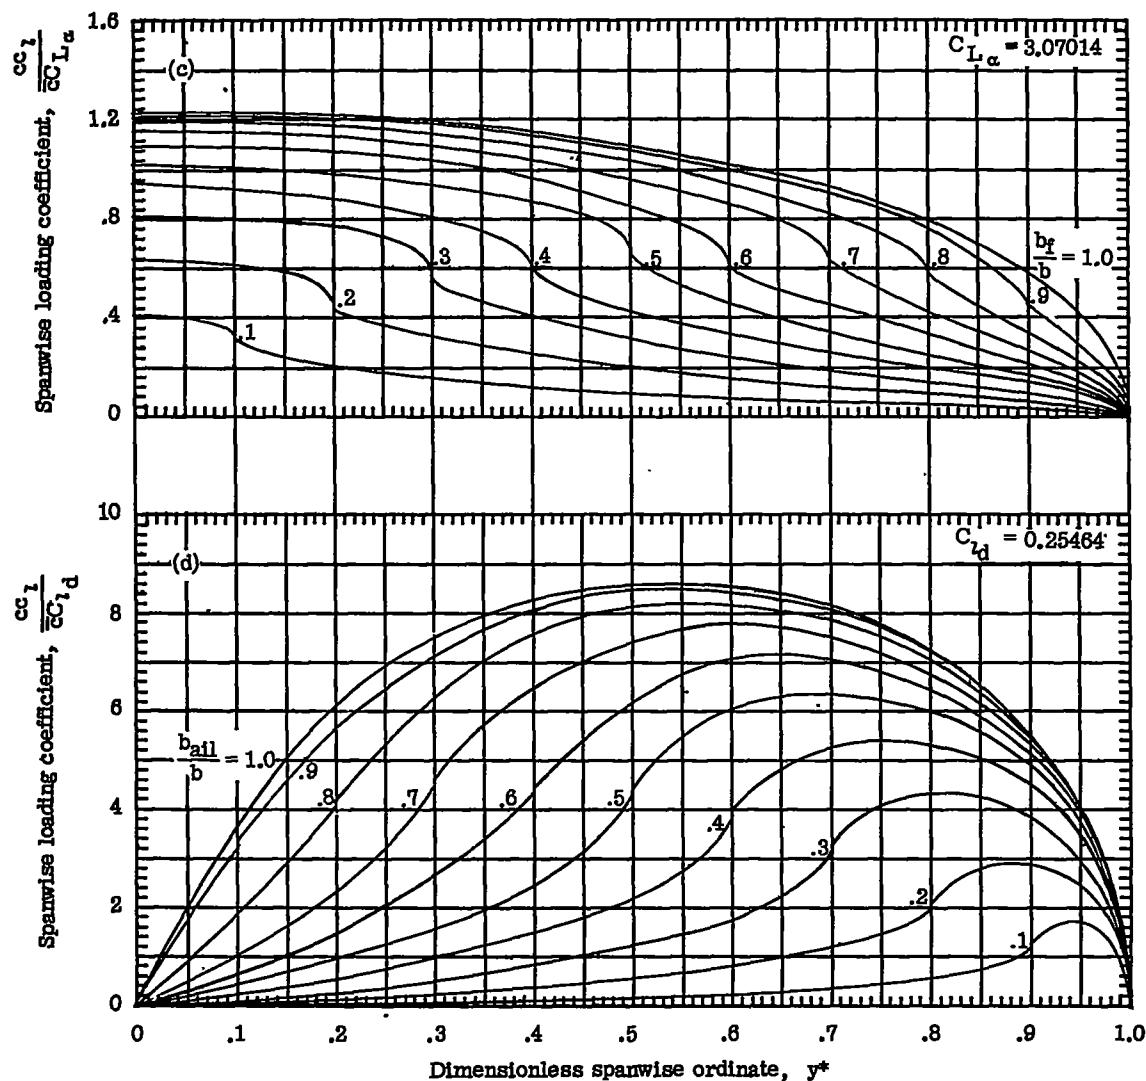

Figure 27.- Concluded.

(a) Symmetric lift distributions.

(b) Antisymmetric lift distributions.

Figure 28.- Spanwise lift distributions for plan form 423 ($A = 3.0$; $\lambda = 0.50$, $\Lambda = 30^\circ$).

(c) Lift distribution for inboard flap.

(d) Lift distribution for outboard aileron.
